The second zone includes from San Jose station to CP Lick. In this section, in which the Tamien station is located, a third track has been designed to the right of the current ones. Horizontal and vertical displacements of the track, of greater magnitude than the previous section, are expected in the works on this area.

Initial Hypothesis

For design the proposed solution, the files used as baseline are listed below:

- Existing layout:
  - X-FJ-TT-ALGN-EXST-Caltrain-2016.dgn.
- Existing geometry:
  - TT-existing-2016.alg. This file set axes MT-1 and MT-2 in the ground plan. The profile of axis MT-1 is the only one established.

Information from this file is limited, it establishes the entire layout in the ground plan, but the profile is only available between Scott and CP Lick.

- Future layouts:
  - X-JM-TT-ALGN-PROP-ALT4-CPCST-CPLK.dgn
- Future geometry:
  - Alt4-CPCST-CPLK.alg. This file set axes MT-0, MT-1, MT-2 and MT-3 in the ground plan. The profiles of axis MT-1 and MT-3 are established.

The collection of construction drawings that accompanies this document shows graphically the different degrees of impact to main tracks in the Scott Boulevard to CP Lick corridor. In them, the scope of the adaptation work for horizontal and vertical layout, turnouts, stations and at-grade crossings is shown.

The distance between existing and proposed tracks is shown on the drawings organized by tracks. The tracks analyzed are:

- College Park Station - San Jose Station. MT-0 new track.
- San Jose to CP Lick. MT-1, MT-2 y MT-3 tracks.

The track shift work analyses is completed with the first three segments of construction phases. From these construction phases is possible establish the action over tracks:

- Displace the existing tracks
- Build new tracks

These actions are shown on the track shift works drawings (JM-CV-I6SSC-TSW). Its used different color to distinguish between both solutions.

The range of track displacements is show with different color. The construction method to use is according to value of displacement. The description of construction methods is show in the General Considerations for Track Works. Point 3.1: *Actions in the horizontal layout*.

The actions in the **longitudinal profile** have been classified by whether the track is raised or lowered. The document General Considerations for Track Works point 3.2 *Actions in elevation* shows the range of vertical displacements. According to vertical displacement this document indicates the construction method to use. The construction methods vary from profile adjust by tamping to rebuild entire section. The range of vertical displacement is show in track shift works drawings.

The initial hypothesis considers that the electrification system to be installed by Caltrain will be executed with catenary posts. This system is not compatible with the proposed final solution because the final solution is proposed with gantries. Therefore, the removal of poles and the installation of a new electrification system executed by gantries has been contemplated.

Due to the number of stations and diversions existing along the track, impacts to the existing **track turnouts** is significant. Changes to turnouts can be classified as those that will remain on the track but that will be adjusted in their horizontal and vertical position, those that will be dismantled and the installation of new turnouts.

All the adjustments that have to do with the turnouts will be carried out in parallel with the actions on the track where it is located. Generally, the actions in turnouts are made during the weekend, since these operations are complex and if any adversity occurs there is more time available to solve it.

There is a large number of turnouts where profile changes are required. The major changes in the horizontal plane are associated with the disassembly and assembly of new turnouts.

APPENDIX H. PROPOSED CONSTRUCTION STAGING AREAS

Index

1. PROPOSED AREAS. 1

1. PROPOSED AREAS.

It has been defined four construction staging areas. These areas are characterized by access to existing roads and proximity to the rail tracks.

The proposed areas are:

1. Lafayette street st 2302+00 near of Santa Clara station
2. Coyote area st 745+00
3. Bailey Ave st 795+00
4. Llagas Creek st 1300+00

These areas and their limits are shown in the follow sheets.

APPENDIX 2-M: GILROY LMF OPTION CONSIDERATION AND ELIMINATION

MEMORANDUM

Date: September 3, 2021

To: Boris Lipkin, Northern California Director
Morgan Galli, Northern California Deputy Director

From: Paul Hebditch[1], Lead Operations Planning and James Tung, San Francisco to San Jose Project Manager

CC: Gary Kennerley, Northern California Director of Projects
Julian Bratina, Northern California Engineering Project Manager

Subject: Gilroy LMF Option Consideration and Elimination

Introduction

This memorandum provides the history of planning for the Light Maintenance Facility (LMF), discusses the design objectives for high-speed rail in Northern California, presents the technical requirements for an LMF, and documents the reasons for eliminating a Gilroy LMF from consideration.

Summary

The proper location of the LMF in a railway system is one of the critical elements in providing a reliable and resilient train service to customers. The LMF must provide easy access for HSR trains onto and off of the network and be located near key service termination locations to support efficient startup of the service each morning and end of service each evening and allow for overnight maintenance of the trains and the infrastructure.

The California High-Speed Rail Authority (Authority) has been studying a potential LMF site in Brisbane (with options on the east and west side of the tracks) since 2010. In response to the Authority's Draft EIR/EIS for the San Francisco to San Jose project section (published in 2020), the City of Brisbane provided comments suggesting the LMF should be (among other options) located in Gilroy. This memo describes the challenges with that location for the Authority, Caltrain, and the other users of the rail corridor between San Francisco and Gilroy (such as freight operators).

Locating the LMF in Gilroy, further away from the terminal station, would increase the distance that non-revenue trains must travel on the system, increase the need for more frequent track maintenance, and impact the operating windows for freight operators. Overall, these extra trains would increase the risk of operating incidents and decrease the reliability of the system. Because every train would need to

[1] Paul Hebditch, CHSRA Rail Operations and Delivery: Paul Hebditch has over 30 years of experience in the railroad industry working in operations roles at all levels. He spent 25 years in the UK railroad industry and in the last 5 years has supported US railroad businesses in California including the California High-Speed Rail Authority as their Operations Planning Lead. He has experience in the development and implementation of operational plans aimed at delivering reliable resilient and efficient rail operations.

travel the length of the corridor from Gilroy to San Francisco for start of its service, the impacts would be felt across the entire rail corridor for all operators and passengers. In addition to these railroad impacts, additional train travel would impact the community through additional gate down times at all vehicular crossings, which would lead to additional traffic delays, and additional noise impacts during overnight noise-sensitive hours. These challenges would be further exacerbated as service ramps up in the corridor, including through Caltrain's 2040 service vision. Other environmental factors considered for the Gilroy location include impacts to the flood plain, wildlife corridors, and agricultural and cultural resources.

Background

The LMF[2] is a critical component of the HSR system and was conceptualized in the initial planning for the San Francisco to San Jose project section in 2010 and again when the environmental review process for the project section was reinitiated in 2016.

While a total of eleven locations for the LMF were initially considered[3] (refer to Figure 1), since 2010 the only feasible options carried forward are the two locations in Brisbane. The Draft EIR/EIS for this project section, released for public review on July 10, 2020, evaluated the two LMF options in the City of Brisbane, with Alternative A on the east side of the tracks and Alternative B on the west side of the tracks (refer to Figure 2). The Alternative A and Alternative B sites in Brisbane satisfy the key engineering, financial, and operational considerations that guide the siting of an LMF. It is approximately eight miles from the terminal station in San Francisco, and the closest location that would not result in severe impacts to existing land uses. The layout was designed to minimize impacts on Caltrain and freight train operations in this heavily utilized rail corridor by providing a grade-separated junction at the entry to the facility. Among several advantages, the Brisbane sites were the only locations along the Caltrain corridor large enough to accommodate the facility needs without displacing existing neighborhoods or other land uses. Alternative A (East Brisbane LMF) was identified as the Preferred Alternative in part based on consideration of the City's plans[4] to put mixed use (including housing) on the west side of the existing rail corridor and the property owner's plans to phase development starting with the west side.

[2] The 2010 Preliminary Alternatives Analysis and 2010 Supplemental Alternatives Analysis referred to the LMF as the Maintenance Facility. Technical Memorandums 5.1 and 5.3 refer to the LMF as the Terminal Storage and Maintenance Facility (TSMF).

[3] The LMF Site Selection Memorandum evaluates 11 total LMF sites and is included in Appendix 2-K. The Preliminary Alternatives Analysis 2010 and Supplemental Alternatives Analysis 2010 evaluated and dismissed the Port Site and SFO.

[4] In November 2018, voters in Brisbane approved Measure JJ which amended the City's General Plan to allow 1,800-2,200 residential units and 7 million square feet of commercial development on the Baylands site. As of the date of this paper, the Specific Plan for the area is still under development.

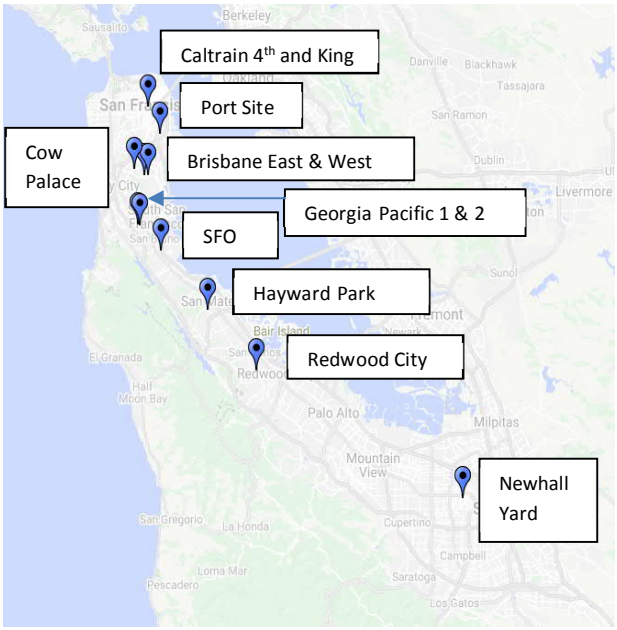

Figure 1: LMF Sites Considered

Figure 2: Alternatives in Draft EIR/EIS

LMF Function and Design Criteria

The LMF analyzed in the Draft EIR/EIS for the San Francisco to San Jose project section is one of only three such facilities[5] that would support the 520-mile Phase 1 high-speed rail system. It would serve as the day-to-day location for overnight storage, maintenance, inspection, and ongoing routine servicing of trainsets. Trains and crews would be dispatched from the LMF to the Salesforce Transit Center (STC), or the interim 4th and King Street Station, to begin revenue service throughout the day. The LMF would house standby trainsets to protect reliable operation and would function as a service point for any trains in need of emergency attention.

The LMF would also support maintenance of trainsets, which occur on a daily, monthly, and quarterly basis to meet federal safety and maintFAenance standards. Maintenance activities include train washing, interior cleaning, wheel truing, testing, and inspections. These activities may occur between runs or as a pre-departure service at the start of the revenue day.

The Authority's design criteria[6] for storage and maintenance facilities are based on best practices and experience gained by other high-speed rail system operators throughout the world. There are three primary criteria that govern the siting and location of the LMF (that would be relevant for consideration of the location between Brisbane and Gilroy): Distance from terminal station, size, and proximity to mainline tracks.

[5] As described in TM 5.3, the three maintenance facilities include: one near the northern terminus in San Francisco, one near the southern terminus in Los Angeles, and one Heavy Maintenance Faciltiy in the centrally located between Merced and Bakersfield.

[6] For more information on LMFs, please consult published Authority technical memoranda (TM). TMs 5.1 and 5.3 related to HSR operation facilities may be found online: https://hsr.ca.gov/programs/environmental-planning/project-level-environmental-engineering-guidelines-studies-reports/

- Distance from terminal station – To support the functions described above, the optimal location for the LMF would be within 1.5–3 miles of the San Francisco terminal station. The system must be designed to minimize the number and duration of non-revenue generating or "deadhead" movements to avoid increased operations and maintenance costs. Deadhead movements also reduce track capacity and revenue train service, and increase community impacts. Close proximity to the terminal station also allows operators to respond more efficiently in emergencies, including midday incidents. While the Brisbane LMF is more than 3 miles from the terminal station, it was the closest feasible location identified.
- Site Size – The LMF sizing criterion is based on ridership projections and fleet size estimates and is intended to be sufficient to handle projected system growth to the year 2040, as identified in the Authority's business plans. Because the LMF is one of three primary maintenance facilities on the high-speed rail system, the capacity of the yard needs to be of sufficient size to accommodate approximately one third of the total fleet size. An area of approximately 100 acres is required to accommodate all necessary components of storage and maintenance at the facility.
- Proximity to mainline tracks – Minimizing the distance between the LMF and the mainline or service tracks is important to reducing costs associated with track infrastructure, minimizing travel time between the mainline track and the LMF, and avoiding or reducing potential effects on existing land uses and environmental resources. The longer the lead track required to access the mainline (> 0.25 mile), the greater the operational and maintenance inefficiencies.

Examples:

For these reasons, railroad systems around the world, including in the US and California, locate storage and maintenance facilities as close as practicable to their terminal stations. For example, in the United Kingdom, the primary depots for almost every high-speed rail service serving London includes a storage and maintenance facility in the inner city suburbs and within ten miles of the main terminal. Two examples are the Great Western at Old Oak Common near Paddington station and the West Coast mainline at Wembley near Euston station. Examples can also be found much closer to home here in California. In California, rail operators, including Metrolink, Amtrak, ACE, and Caltrain, have maintenance facilities within close proximity to their stations. See Table 1, for a example list of California train operators' maintenance facility distances.

Table 1: California Examples of Maintenance Facility to Station Distances

Operator	Maintenance Facility Location/Name	Nearest Station	Distance
Metrolink	Central Maintenance Facility	LA Union Station	2 miles
	Eastern Maintenance Facility	San Bernardino	< 1 mile
	Oceanside (OSD)	Oceanside	2 miles
	Lancaster	Lancaster	< 1 mile
	Ventura	Ventura	< 1 mile
	Perris	Perris	< 1 mile

	Riverside	Riverside	< 1 mile
Amtrak Pacific Surfliner	8th Street Yard Los Angeles	LA Union Station	< 1 mile
	San Diego (SDG)	San Diego	< 1 mile
North County Transit District	Oceanside (OSD)	Oceanside	2 miles
	San Diego (SDG)	San Diego	< 1 mile
Amtrak San Joaquin	West Oakland	Oakland	< 1 mile
	Fresno	Fresno	< 1 mile
	Bakersfield	Bakersfield	< 1 mile
ACE	Stockton	Stockton	< 1 mile
	Tamien	San Jose	2 miles
Caltrain	San Jose Centralized Equipment Maintenance and Operations Facility	San Jose	< 1 mile
	SF 4th and King	SF 4th and King	< 1 mile
Capital Corridor	Sacramento	Sacramento	< 1 mile
	West Oakland	Oakland	< 1 mile
	Oakland Coliseum	Oakland Coliseum	< 1 miles
	San Jose	San Jose	< 1 mile

For California high-speed rail service, the key terminating points will be San Francisco and Los Angeles, at STC and LAUS, respectively. In Los Angeles, the Authority is proposing a storage and maintenance facility in the West Yard area, which is within one mile of LAUS. Even at less frequently used terminating locations, such as Merced and Anaheim, the Authority has designed the system in line with international best practices by ensuring that storage and maintenance facilities are in close proximity the terminal stations.

For its northern terminus in San Francisco, the Authority undertook an extensive search to identify an appropriate location for the northern-most maintenance facility. This assessment determined that the sites at Brisbane are the most consistent with operating requirements and avoid intensive existing land uses on the Peninsula.

Operational Consequences of an LMF Located in Gilroy

The LMF is a heavily utilized facility, and Gilroy is not a functionally appropriate location because it is located approximately 80 miles south of the terminal facility. As described below, a Gilroy LMF would add additional risk to the reliability of operations, increase the risk at each of the 70 grade crossings located between San Francisco and Gilroy, increase gate down time, and increase the cost of operations.

Transportation from a Gilroy LMF to the terminal station in San Francisco for the start of daily services and back to the facility at the end of daily service would require an additional 27 deadhead trains per

day to be added to the 124 revenue trains per day to be scheduled on the Caltrain corridor. This represents nearly a 25% increase in the number of high-speed train movements on the entire Caltrain corridor. The additional deadhead movements are summarized and discussed below:

Table 2: Deadhead Movement Assessment

Deadhead miles to Brisbane	240 miles per day
Deadhead miles to Gilroy	2,111 miles per day
Additional deadhead miles for Gilroy LMF	**683,000 miles per year**
First deadhead move departs Brisbane	5:20am to make 6:00am start of service
First deadhead move departs Gilroy	4:25am to make 6:00am start of service
Last deadhead move arrives Brisbane	Leave STC at 12:09am and arrival at 12:40am
Last deadhead move arrives Gilroy	Leave STC at 12:45am and arrival at 1:55am
Additional time of operations	**130 minutes per day**
Additional energy cost per day (@43kWh/mile and $0.074 per kWh)	$7,828
Additional trainset maintenance cost per day (@ $1.077 per mile)	$2,649
Additional traincrew costs per day (@ $75 per hour)	$2,250
Total additional costs	**$12,727 per day ($4.7million per year)**

The additional deadhead miles add a certain amount of risk to the operational objective of providing safe and reliable train operations in several ways. The additional trains would extend the operating period by an additional 130 minutes, thereby reducing the amount of time for track/train maintenance from 6 hours to just under 4 hours. The extra train movements would degrade the system faster but allow less time to provide maintenance. This inverse relationship significantly increases the risk for providing reliable train operations.

For rail corridors, the greatest risk occurs at interfaces with other modes of transportation. There are 70 grade crossings between San Francisco to Gilroy and only 2 grade crossings between San Francisco to Brisbane. By placing the LMF in Gilroy, the number of trains passing through grade crossings increases, thereby increasing the risk of incidents.

Furthermore, when there is an incident or during emergency train servicing scenarios, the train would, to the best of its ability, complete the trip to the terminal station in San Francisco before heading to the LMF. A LMF located in Gilroy would make this journey significantly more challenging and riskier for a train in need of servicing.

The train slots required by these movements would also absorb the limited capacity on the two-track railway corridor between Gilroy and San Francisco. Since the deadhead moves would occur after midnight and before 6am, they would have less effect on passenger revenue service. However, Caltrain conducts non-revenue moves of their trains overnight so capacity for those moves would be affected. The reduced capacity would also affect the window of operation for freight operators, which primarily

operate in the evening and overnight hours in the Caltrain corridor. These operators are also looking to increase future operations.

Finally, the additional distance that high-speed trains would need to travel (estimated at around 683,000 miles per year) would increase wear and tear, resulting in increased track and system maintenance costs for Caltrain as the infrastructure owner, and increased trainset maintenance costs for the Authority as the trainset owner. The Authority would also incur additional costs associated with additional traincrew and traction power requirements. The Authority estimates that total annual operating costs increase for full-service operations would be approximately $4.7 million. These additional costs would need to be recovered through the fare box for the Authority to meet its Proposition 1A requirement to operate without subsidy. Therefore, locating the LMF facility in Gilroy, rather than Brisbane, would directly impact ticket prices for customers.

Environmental Impacts of a Gilroy LMF

Several environmental considerations were factored into the study of LMF locations, including the Gilroy location. Below is a description of Gilroy location specific impacts followed by corridor wide (from San Francisco to Gilroy) impacts.

Location Specific Impacts

The Gilroy LMF was removed from the San Jose to Merced project with the change in program delivery direction and definition of the "Valley to Valley" section in the 2018 Business Plan. When the Valley to Valley Section changed the temporary terminal station in San Jose to a terminal station San Francisco, there no longer was an operational need to have an LMF in Gilroy. By removing the LMF from the San Jose to Merced environmental analysis, the project section's overall impacts to the following resources was minimized:

Flood Plain Impact:

Given the space requirements, a Gilroy LMF would need to be located in the Soap Lake Flood Plain, just as the Maintenance of Way Facility for each of the alternatives. During a 100-year flood event, flooding in the Soap Lake area has the potential to submerge approximately 9,000 acres. The additional encroachment of an LMF into the floodplain and additional impervious surfaces added in the floodplain would increase project effects on hydrology and water quality.

Biological Resources:

A Gilroy LMF would be located in a natural wildlife corridor associated with the lands to the south and east of Gilroy in the Soap Lake Floodplain, including the Pajaro River. This area is a valley, allowing wildlife to migrate between the Diablo Range to the east and the Santa Cruz Mountains to the west. The importance of this wildlife movement corridor to the populations of rare and common species have been documented through the work of the Santa Clara Valley Habitat Conservancy, the Nature Conservancy, and other organizations. The placement of a Gilroy LMF in this wildlife corridor would increase the project's effects on wildlife movement and require increased and more ambitious mitigation efforts. In contrast, the existing conditions of the proposed LMF location for the Preferred Alternative in Brisbane is an area of a former landfill and has much lower habitat value than the land to the south and east of Gilroy.

Agricultural Resources:

A Gilroy LMF would be located in an area of primarily agricultural resources. A Gilroy LMF would require more ambitious mitigation for such effects. In contrast, the existing conditions of the proposed LMF location for the Preferred Alternative in Brisbane is in an area of a former landfill.

Cultural Resources:

A Gilroy LMF would be located in the Soap Lake Flood Plain. This is an area that has been documented as a tribal cultural resource, a sacred place with cultural value to a California Native American tribe and is an archeologically sensitive area. Section 106 requires that this be taken into consideration with any federal project. A Gilroy LMF would require more encroachment into this sensitive area, more construction and disturbance in this archaeologically sensitive area, and potentially more impacts to tribal and archaeological resources. In contrast, the proposed LMF location for the Preferred Alternative in Brisbane is in an area of a former landfill and is not a sensitive area for tribal or archaeological resources.

Corridor Wide Impacts

The corridor wide impacts affect all the communities between San Francisco to Gilroy. As described above, this spans approximately 80 miles and 70 grade crossings.

Transportation and Traffic Impacts:

An LMF facility located in Gilroy would result in substantial deadhead train travel to and from San Francisco, the northern terminus. These increased train movements would increase the potential for incidents at 70 grade crossings between San Francisco and Gilroy, thereby increasing the risk of delay for all rail services on the Caltrain corridor. This could lead to a decline in on-time performance of all services on the Peninsula. If an incident occurs, operational protocol requires the damaged train to go to the terminal station in San Francisco to drop off passengers and then go to the LMF for servicing. Locating the LMF in Gilroy would exacerbate this issue. Not only does this location for the LMF increase the risk of incidents, it makes it harder to recover from them if they occur.

Furthermore, increasing the number of trains at the crossings directly increases gate down time. A gate is down for approximately 1 minute every time a train passes through. 27 extra trains would increase gate down time by approximately 27 minutes per day at all 70 grade crossing between San Francisco to Gilroy. In contrast, an the 27 extra trains would only affect 2 grade crossings with the LMF in Brisbane.

Safety and Security

The Authority received feedback from first response organizations regarding the potential impact on response times in this area from the increased service levels currently proposed for the San Jose to Merced project section. Locating the LMF in Gilroy would exacerbate this issue for all 70 grade crossings between San Francisco to Gilroy. Each gate crossing takes approximately a minute to open and close, depending various site-specific issues such as the speed of the train at that location, potential trains on the adjacent track, and proximity to station platforms. 27 additional trains per day per direction would increase gate down time by 27 minutes per day at each of the 70 grade crossings.

Noise:

The increase in deadhead train movements would increase overnight and early morning train noise along the rail corridor due both to train movements and the sounding of horns. Trains are mandated by FRA rules to sound their horn at every grade crossing, resulting in more frequent horn noise. This noise

would occur during the more noise-sensitive overnight and early morning hours with the deadhead train movements to a Gilroy LMF. These additional noise effects are avoided with an LMF in Brisbane, because the LMF would be located close to the northern California terminus for the HSR system in San Francisco, which reduces the areas affected by deadhead moves compared to an LMF in Gilroy.

1 INTRODUCTION

Since publication of the Draft Environmental Impact Report (EIR)/Environmental Impact Statement (EIS), the following substantive changes have been made to this appendix:

- This appendix was updated to correct two typographical errors in Table 6.
- The results of additional analysis with the planned intersection at Dunne Avenue and Depot Street/Church Street per the City of Morgan Hill General Plan were added to Table 16.
- Table 17, 2040 No Project and Plus Project Mitigated Level of Service at Intersections in San Jose Diridon Station Approach, Monterey Corridor, Morgan Hill and Gilroy, and San Joaquin Valley Subsections, was added.

This appendix provides technical data and figures related to the assessment of intersection and freeway delays for the San Jose to Merced Project Section.

It should be noted that Senate Bill (SB) 743 was signed into law on September 27, 2013, the transportation impact analysis under the California Environmental Quality Act (CEQA) shifted away from auto delay toward consideration of greenhouse gas reductions, with a focus on multimodal transportation networks and land use mixes. Vehicle Miles Traveled (VMT) was chosen as the new metric for evaluating transportation impacts under CEQA. SB 743 does not prevent counties or cities from continuing existing transportation impact analyses, including use of vehicular LOS in their general plans, but for CEQA analysis, lead agencies are required to shift to a VMT metric by July 1, 2020. Therefore, intersection and freeway LOS was not considered for CEQA impacts.

However, since the environmental document is a combined document for the purposes of both CEQA as well as the federal National Environmental Policy Act (NEPA), intersection and freeway delays were evaluated to determine project effects under NEPA and this appendix provides the technical data supporting that analysis.

2 FREEWAY MAINLINE SEGMENT OPERATIONS

Freeway levels-of-service (LOS) operations were evaluated. Freeway segments that would serve 100 or more project-generated trips in either the AM or PM peak hour were analyzed. Analysts assessed both freeway mainline segments using the methodologies described in the *Highway Capacity Manual* (Transportation Research Board 2010). Analysts evaluated freeway mainline segments using the method described in Chapter 11 of the *Highway Capacity Manual* (Transportation Research Board 2010). The detailed methodology is presented in Section 3.2.4.3 of the San Jose to Merced Project Section Environmental Impact Report/Environmental Impact Statement.

Analysts identified effects on the freeway system through a two-step process. First, the LOS was determined using the volume to capacity (V/C) ratio, as shown in Table 3.2-7 in Section 3.2.4.3 of the San Jose to Merced Project Section. Then, for freeway segments with LOS E or F (only), the difference in the V/C ratio between the No Project and Plus Project conditions was calculated. An effect was deemed to occur if the project caused the V/C ratio to increase by 0.04 (4 percent) or more.

Freeway operations were studied under the following conditions:

- Existing Conditions
- Existing Plus Project Conditions (effects from permanent road closures and relocations)
- 2029 No Project Conditions
- 2029 Plus Project conditions (effects from permanent road closures and relocations, and Project operations)
- 2040 No Project Conditions
- 2040 Plus Project conditions (effects from permanent road closures and relocations, and Project operations)

Entries **bolded with an asterisk (*)** identify location experience LOS E or F in one or both peak hours.
US = U. S. Highway
SR = State Route
SB = southbound
OS = level of service
V/C = *volume-to-capacity ratio*
Bolded entries identify location *experience LOS E or F in one or both peak hours.*

FEBRUARY 2018

Figure 1 Monterey Corridor Affected Freeway Segments

3 INTERSECTION OPERATIONS

The operation of intersections is based on various intersection characteristics such as traffic volumes, lane geometry, and signal phasing, which are used to estimate the average control delay experienced by motorists traveling through an intersection. Intersection levels-of-service (LOS) operations were evaluated. Intersections of roadways classified as a collector or above that would be physically modified by the project or would serve 50 or more project trips in either the AM or PM peak hour were analyzed. Analysts evaluated traffic conditions at intersections using the method from Chapter 19 of the *Highway Capacity Manual* (Transportation Research Board 2010). The detailed methodology is presented in Section 3.2.4.3 of the San Jose to Merced Project Section Environmental Impact Report/Environmental Impact Statement.

An effect on signalized intersections was deemed to occur if the Plus Project condition would result in a LOS E or F and an increase in average traffic delay of 4 seconds or more over the No Project condition. An effect on unsignalized intersections was deemed to occur if the Plus Project condition would have a LOS E or F and the project would result in an increase in traffic delay of 5 seconds or more (measured as average delay for all-way stop or worst-movement delay for side-street stop intersection), and if the intersection satisfies one or more traffic signal warrants[1] for at least 1 hour of the day. Five seconds of delay is the increase for unsignalized intersections (rather than the 4 seconds used for signalized intersections) because it only applies to a single movement rather than for the entire intersection, as is the case for signalized intersections.

Intersection operations were studied under the following conditions:

- Existing Conditions
- During construction on Monterey Road (effects due to construction of the narrowing of Monterey Road)
- Existing Plus Project Conditions (effects from permanent road closures and relocations)
- 2029 No Project Conditions
- 2029 Plus Project conditions (effects from permanent road closures and relocations, and Project operations)
- 2040 No Project Conditions
- 2040 Plus Project conditions (effects from permanent road closures and relocations, and Project operations)

[1] Traffic signal warrants define minimum conditions under which signal installation may be justified.

Entries **bolded with an asterisk (*)** identify location experience LOS E or F in one or both peak hours.

LOS = level of service
SR = State Route
I- = Interstate
NB = northbound
SB = southbound
WB = westbound
CT= California Department of Transportation
CMP = Congestion Management Plan
MH = City of Morgan Hill
G = Gilroy
SCCo = Santa Clara County
Ext. = Extension
SSSC = side street stop controlled
AWSC = all-way stop controlled
Alts = alternatives
TBD = to be determined
MOWF = maintenance of way facility
facility
--- = Intersection does not exist

LOS = level of service
SB = southbound
NB = northbound
EB = eastbound
WB = westbound
[1] Affected intersections are shaded in grey.
[2] LOS and delay results are based on changes in roadway capacity and the shifting of traffic from temporary lane closures and relocations during construction.
Entries **bolded with an asterisk (*)** identify location experience LOS E or F in one or both peak hours.
Shaded entries bolded with double asterisks (**) identify locations with project effects per the criteria.

LOS = level of service;
EB = eastbound; SB = southbound; WB = westbound; NB = northbound
SR = State Route
US = U.S. Highway
I = Interstate
Whole intersection average delay reported for signalized intersections. Whole intersection average delay and worst approach delay (in parentheses) reported for unsignalized intersections.
Entries **bolded with an asterisk (*)** identify location experience LOS E or F in one or both peak hours.
Shaded entries bolded with double asterisks (**) identify locations with project effects per the criteria

Whole intersection average delay reported for signalized intersections. Whole intersection average delay and worst approach delay (in parentheses) reported for unsignalized intersections.
Entries **bolded with an asterisk (*)** identify location experience LOS E or F in one or both peak hours. LOS = level of service; SR = State Route; I- = Interstate
NB = northbound; SB = southbound; EB = eastbound; WB = westbound
SJ = City of San Jose
CT= California Department of Transportation
CMP = Congestion Management Plan
MH = City of Morgan Hill
G = Gilroy; SCCo = Santa Clara County; LB = City of Los Banos
MCo = Merced County
SSSC = side street stop controlled
AWSC = all-way stop controlled
Alts = alternatives
TBD = to be determined
MOWF = maintenance of way facility
Ext. = Extension
--- = Intersection does not exist

Whole intersection average delay reported for signalized intersections. Whole intersection average delay and worst approach delay (in parentheses) reported for unsignalized intersections.
*Entries **bolded with an asterisk (*)** identify locations with LOS E or F in one or both peak hours. **Shaded** entries bolded with double asterisks (**) identify locations of effects under NEPA as defined by the criteria.*
SR = State Route
I- = Interstate
NB = northbound
SB = southbound
EB = eastbound
WB = westbound
LOS = level of service
MOWF = maintenance of way facility
Ext. = Extension
US = U.S. Highway
--- = Intersection does not exist.

This Page Intentionally Left Blank

Whole intersection average delay reported for signalized intersections. Whole intersection average delay and worst approach delay (in parentheses) reported for unsignalized intersections.
Entries **bolded with an asterisk (*)** identify location experience LOS E or F in one or both peak hours.
LOS = level of service
SR = State Route
I- = Interstate
NB = northbound
SB = southbound
EB = eastbound
WB = westbound
SJ = City of San Jose
CT= California Department of Transportation
CMP = Congestion Management Plan
MH = City of Morgan Hill
G = City of Gilroy
SCCo = Santa Clara County
LB = City of Los Banos
MCo = Merced County
SSSC = side street stop controlled
AWSC = all-way stop controlled
Alts = alternatives
TBD = to be determined
MOWF = maintenance of way facility
Ext. = Extension
--- = Intersection does not exist

Whole intersection average delay reported for signalized intersections. Whole intersection average delay and worst approach delay (in parentheses) reported for unsignalized intersections.
*Entries **bolded with an asterisk (*)** identify locations with LOS E or F in one or both peak hours.* **Shaded** *entries bolded with double asterisks (**) identify locations of effects under NEPA as defined by the criteria.*
[1] The City of Morgan Hill's 2030 General Plan includes an infrastructure project that would combine the existing off-set intersections of Dunne/Church and Dunne/Depot to one four-legged intersection of Dunne/Church/Depot. With this change, the new intersection would function at LOS C/21.4 and LOS C/29.9 during the AM and PM peak hours respectively during the 2040 No Project Condition. Under the 2040 Plus Project Alternative 4 Condition the new intersection would function at LOS C/22.5 and LOS C/31.1 during the AM and PM peak hours respectively.

APPENDIX 3.2-B: VEHICLE MILES TRAVELED FORECASTING

CALIFORNIA High-Speed Rail Authority

Memorandum

DATE: January 22, 2020

TO: Memo to File

FROM: John Helsel, Travel Demand Forecasting for the RDP 2017-2019

SUBJECT: Further Background on Cambridge Systematics Explanation of Ridership Forecasts

Cambridge Systematics, Inc. (CS) developed the ridership and revenue forecasting model used to support the 2016 Business Plan. This model was named the Business Plan Model – Version 3 (BPM-V3) and is documented separately. The BPM-V3 was also used to estimate changes in vehicle miles traveled (VMT) for the California High-Speed Rail Authority (the Authority) to support various environmental planning efforts. CS documented its efforts in the main document which this memo accompanies.[1]

The CS ridership, revenue, and VMT forecasts were used as the core input to produce year-by-year estimates by the Rail Delivery Partner (RDP) for use by the Authority. This memo documents the reason and methodology for the process by which the CS inputs were used to create the year-by-year estimates.

Application of CS Forecasts

The CS forecasts for the 2016 Business Plan formed the basis for the forecasts of ridership, revenue, and VMT used by the Authority but had to be aligned with the required application in business plan and environmental analysis as follows:

- The Business Plan cash flow analysis and environmental planning groups required annual forecasts for every year between the start of operations and 2060 (while CS forecasts were developed only for three individual years and not for every year between the start of operations and 2060); and,

- The Business Plan cash flow analysis and environmental planning groups required a set of reasonable ramp-up assumptions to account for the introduction of new services (the BPM-V3 model assumes a steady-state system). These ramp-up assumptions reflect the reality that transit systems experience a transition over their initial operation as new riders begin to incorporate the system into their travel planning. This is especially likely to be true with HSR because it will be a new mode for most travelers and not merely an extension of an existing system.

The BPM-V3, like most travel demand models, delivers forecasts for a single typical day, which are then annualized to estimate annual travel behavior. Each forecast requires socioeconomic, land use, and transportation network data for the year of the forecast. Each forecast also requires processing time of about a week on a high performance computer. It is unreasonable to produce individual year forecasts when the only input changes are the baseline socioeconomic, land use, and transportation network data. Instead, the RDP directed CS to provide forecasts for three model years and then interpolated forecasts for the years not explicitly modeled.

[1] Cambridge Systematics. October 4, 2019. *California High Speed Rail Environmental Analysis: Method for Forecasting Vehicle-Miles of Travel Reductions.*

Methodology for Transition from CS Single-Year Forecasts to Multi-Year Forecasts

The methodology to estimate vehicle miles traveled (VMT) from the ridership model was driven by the methodology to estimate overall ridership. These two efforts were tied together in order to make the year-by-year estimates as consistent and theoretically coherent as possible. Thus, this section will discuss both the original estimates for ridership and then highlight to additional effort to derive forecasts for VMT.

In 2016, CS provided forecasts for three years (2025, 2029, and 2040).[2] Since the 2016 Business Plan forecasts were developed, the Authority has adopted its 2018 Business Plan, which was accompanied by updated forecasts. The 2016 and 2018 Business Plan ridership forecasts were developed using the same travel forecasting model; the forecasts differ due to changes in the model's inputs, including the high-speed rail service plan, demographic forecasts, estimates of automobile operating costs and travel times, and airfares.

Forecasts of the Valley-to-Valley line (San Francisco to Bakersfield) were provided for its first and last years of operation (when Phase 1 would come online): 2025 and 2029. Forecasts for the Phase 1 line (San Francisco to Anaheim) were provided for its first year of operation and a reasonable out year for forecasts: 2029 and 2040.

To develop the ridership and revenues series shown in the Business Plan[3], the RDP took the forecasts for Valley-to-Valley and Phase 1 and developed a compound annual growth rate (CAGR) for the two systems between the modeled years. These were calculated to be 0.10% for Valley-to-Valley and 1.33% for Phase 1. Ridership growth after 2040 was assumed to be 1% annually through 2060. This series represented the steady state for ridership on the system without accounting for the ramp-up of introducing new services.

However, it is well documented that it takes time for riders to reach these steady state behaviors and so ramp-up factors were applied to ensure that the Authority would report reasonably conservative forecasts during initial operation. The full set of assumptions for the ridership ramp-up are reported in the 2016 Business Plan, but are repeated here for completeness. The RDP used a 5-year ramp-up cycle (40%, 55%, 70%, 85%, and 100%). From 2025-2028, this series was applied in a straightforward manner. From 2029 to 2034, when Phase 1 was introduced, the ramp-up applied only to the difference in ridership between Valley-to-Valley and Phase 1. In other words, the ridership that used the system during Valley-to-Valley operation was assumed to continue to use the system without alteration, but the additional ridership from the larger system was incremental.

Importantly, the RDP did not estimate any differentials in which markets would be affected during the ramp-up periods. The ramp-up cuts were applied to the headline system-wide ridership and revenue values and assumed to apply evenly.[4]

The forecasted VMT and vehicle hours traveled (VHT) *reductions* (relative to the No Build scenario without high-speed rail service) were adjusted to be consistent with this methodology. First, CS provided Build and No Build VMT and VHT totals and by county for each scenario as well as the reduction in VMT

[2] A full description of the assumptions and modeling efforts for the 2016 Business Plan can be found in the Technical Memo attached to that plan on the Authority's website: https://hsr.ca.gov/docs/about/business_plans/2016_Business_Plan_Ridersihp_Revenue_Forecast.pdf.

[3] See Exhibit 7.1 to Exhibit 7.10 in the Business Plan: https://hsr.ca.gov/docs/about/business_plans/2016_BusinessPlan.pdf.

[4] The BPM-V3 was developed to estimate steady-state travel conditions. Ramp-up periods vary depending on ridership markets, competitive situation and existing ridership experience. While it was reasonable to use the steady-state condition as an upper bound of ridership, it was not well suited to the task of determining how particular sectors might react during the ramp up period. For instance, it may be that people living in San Jose will immediately begin using the system to travel to San Francisco because it is very similar to existing Caltrain service. And it may come to pass that people living in Bakersfield will be slightly slower to adopt HSR because it would be a much newer mode. The model did not have any data to support such differentiated approaches and the magnitude of ramp-up and so the decision was made to just apply the ramp up percentage evenly across all ridership markets and geographies.

and VHT (i.e., the difference between the Build and No Build scenarios).[5,6] Second, the reduction in VMT and VHT was modeled using the CAGR developed for overall ridership and the No Build VMT and VHT were increased using a CAGR between the No Build scenarios (and assumed to grow at 1% post 2040). Again, no attempt was made to identify any differences in trip-making patterns during the ramp-up period so all VMT/VHT estimates were factored at the same rate. Finally, the Build VMT was then re-derived as the difference between the No Build and the reduction. Because the reductions were streamed using the ridership CAGR rather than developing a VMT reduction specific CAGR, it is not surprising that the estimate slightly differed from the CS forecast, especially by 2040.[7]

Conclusion

The RDP has produced numerous forecasts of ridership, revenue, and environmental impacts in support of the Authority's mission to deliver high speed rail to California. These forecasts begin with the Authority's service plans for trip times and frequency, are evaluated in the BPM-V3 to find a steady state forecast for several future years, and then interpolated according to the methodology outlined in this memo to meet the needs of the Authority's stakeholders. These interpolations are conservative adjustments to the raw model outputs and represent a reasonable compromise between the BPM-V3's technical limitations and the Authority's business planning needs.

[5] It should be noted that the structure of the travel model provides a forecast for the *change* in VMT/VHT, but does not explicitly provide a forecast for total statewide no build or build VMT/VHT. The BPM-V3 is a long-distance trip model that forecasts all trips longer than 50 miles and shorter trips only in Los Angeles and the San Francisco Bay Area. This has caused some confusion when reporting county wide VMT/VHT where some counties are modeled in the short distance trip model and others are only modeled in the long-distance trip model. The full details of the BPM-V3 short and long distance models can be found in the model documentation: https://hsr.ca.gov/docs/about/ridership/CHSR_Ridership_and_Revenue_Model_BP_Model_V3_Model_Doc.pdf

[6] The raw CS data is found in tables 2.7 and 2.8 in the memo cited in Footnote 1.

[7] The medium case 2040 annual statewide total estimated VMT reductions produced as a result of using the same CAGR used for the ridership series resulted in a reported savings of 4.767 billion VMT reduced. The medium 2040 annual statewide VMT reductions estimated as a direct output of the BPM-V3 were 4.785 billion VMT reduced. Thus, the methodology adopted by the RDP understated the project's impact by 0.35% compared to the VMT seen in the raw model output.

1.0 Travel Modeling Approach

Since 2007, Cambridge Systematics (CS) has been supporting the California High-Speed Rail Authority (Authority) by producing ridership and revenue forecasts for different high-speed rail (HSR) service options. CS developed the "Version 1" model, which was estimated and calibrated using data from the 2000-2001 California Household Travel Survey (CSHTS) and stated-preference (SP) survey data from a revealed preference/stated preference (RP/SP) survey conducted in 2005 for the express purpose of HSR ridership and revenue forecasting.[1] The Version 1 model was used to support alternatives analyses and project-level environmental work.

In preparation for the 2012 Business Plan, CS updated the Version 1 model based on a new trip frequency survey of long-distance travel made by California residents and recalibrated it to 2008 conditions. The enhancements culminated in ridership and revenue model runs used to support the California High-Speed Rail 2012 Business Plan.[2]

In 2012 and 2013, CS made additional enhancements to the ridership and revenue model to accommodate the evolving forecasting needs of the Authority, including the 2014 Business Plan. The enhanced model, known as the Version 2 ridership and revenue model, represented a major overhaul of all model components and incorporated new and reanalyzed data from the 2012-2013 CSHTS and the 2005 SP and revealed preference (RP) data. The enhancements to the Version 2 model incorporated the recommendations of the Authority's Ridership Technical Advisory Panel (RTAP) and considered comments from the Authority's Peer Review Group (PRG) and the Government Accountability Office's report. In addition to the ridership and revenue model enhancements, CS developed a risk analysis approach to estimate uncertainty in the forecasts and prepare and present ridership and revenue forecasts.

Since application of the Version 2 model in the 2014 Business Plan, CS updated the model to the current Business Plan Model-Version 3 (BPM-V3)[3]. During the development of the 2014 Business Plan, CS completed a new 2013-2014 RP/SP survey that was incorporated into the BPM-V3 model.[4] The BPM-V3 was estimated using data from the 2013-2014 RP/SP survey in addition to the 2005 RP/SP survey and the 2012-2013 CSHTS data. Additionally, the model includes an adjustment to explicitly divide auto costs by an assumed average auto occupancy of 2.5 for those who travel in groups.

Finally, based on model applications using the Version 2 model, CS identified a tendency of the model to forecast trips with long access and/or egress times, coupled with relatively short trips on the main mode. This tendency did not show up in the model calibration or validation since most observed trips on conventional rail (CVR) were relatively short and, conversely, most trips by air were relatively long. Since

[4] Cambridge Systematics, Inc., Corey, Canapary and Galanis Research, and Kevin F. Tierney, *California High-Speed Rail 2013-2014 Traveler Survey – Survey Documentation*, prepared for the California High-Speed Rail Authority, February 2015.

HSR provided competitive service for the full range of distances, trips by HSR were more likely affected by the long access-egress/short main mode issue and, thus, the issue was not identified until model application.

In response, CS made enhancements to the BPM-V3 by including four new variables in the mode choice utility functions: auto access time, non-auto access time, auto egress time, and non-auto egress time with each being divided by total auto distance. These variables appear in the access and egress utility components of the mode choice model. The BPM-V3 model was used to produce forecasts of total ridership and revenue primarily for 2016 business planning purposes.

1.1 Approach for VMT and GHG Calculation

1.1.1 2016 Business Plan Ridership Modeling

CS used the BPM-V3 to develop ridership and revenue forecasts[5] for two main phases of the project as specified by the Authority:

1. Silicon Valley to Central Valley (VtoV) – San Jose to a station north of Bakersfield opening in year 2025.
2. Phase 1: San Francisco and Merced to Los Angeles and Anaheim opening in 2029 and an out-year of 2040.

Ridership and revenue forecasts were prepared for the opening year for each implementation step and a Phase 1 out year. The 2016 Business Plan lays out an implementation strategy that starts with the Silicon Valley to Central Valley line. The 2040 forecast reflects ridership on a mature system that would at the time have more than 10 years of operating history.

As noted, the BPM-V3 was used to forecast ridership and revenue for the 2016 Business Plan. The BPM-V3 is a detailed travel model for long distance trips greater than or equal to 50 miles in length made within California on an average day. Four model components are used to estimate the travel:

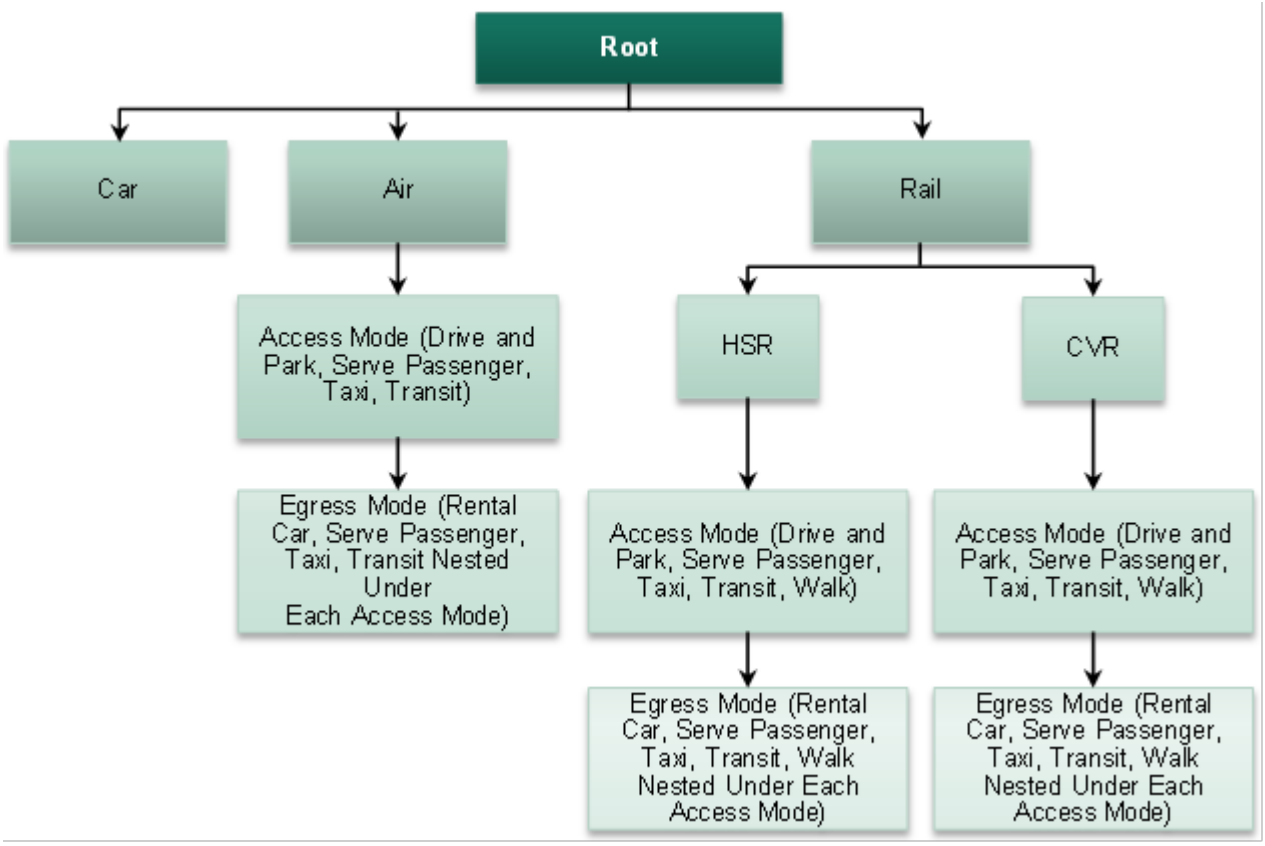
- Trip frequency choice – the choice of making either zero or one long distance trip (e.g., home to work) by residents of California
- Trip destination choice – given that a long-distance trip is being made, what is the destination of that trip from the trip-makers' home locations
- Main mode choice – given a long-distance trip from a trip-makers' home to a specified destination, what mode is used for the travel: auto, air, conventional rail, or high-speed rail
- Access/egress mode choice – given a long distance trip by air, conventional rail, or high-speed rail, what are the access and egress modes used to get to and from the airports or rail stations used for the travel: drive and park (from home to departure airport/station), rental car (from arrival airport/station to destination), dropped off/picked up by auto, or transit.

[5] Detailed ridership and revenue forecast assumptions and results for the 2016 Business Plan are documented in: https://www.hsr.ca.gov/docs/about/business_plans/2016_Business_Plan_Ridersihp_Revenue_Forecast.pdf.

The final model component steps are crucial in understanding forecasts performed using the BPM-V3. Figure 1.1 shows the model structure for the joint mode choice and access/egress choice model. In the figure, "Root" represents trips made by individuals with common household characteristics for (see Section 1.2.2) for a specific TAZ to TAZ interchange. Information regarding the travel options for the interchange, including egress from the best destination station or airport and access to the best origin station or airport for each of the main public transportation modes (air, CVR, and HSR) feeds up through the modeling process and is considered along with the travel characteristics for the main modes. Based on the information, the joint model is used to estimate the probabilities of auto, air, and rail travel for the long-distance trips, then under rail, the probabilities of using CVR or HSR, and then under each of the main modes the probabilities of using each of the available access and egress modes. The number of long distance trips for the individuals making the trips are multiplied by the probabilities to estimate trips by each of the main modes and access/egress modes.

The key is that improvements to travel characteristics for access to or egress from a main mode or changes to the travel characteristics for a main mode proportionally affects the competing modes. Thus, the introduction of HSR for an interchange will proportionally divert travel from both auto and air to rail (the rail travel characteristics are based on both the HSR and CVR characteristics). Further, the rail trips will split between HSR and CVR based on the quality of service and other characteristics afforded by those modes.

Figure 1.1 Nesting Structure for Joint Main Mode – Access/Egress Mode Model



Source: Cambridge Systematics

The long-distance person-trips are modeled for each of four trip purposes:

- Business – trips made from home to another location on an infrequent basis for work-related purposes
- Commute – trips made from home to another location on a regular basis for work
- Recreation – trips made from home to another location for recreational purposes
- Other – trips made from home to another location for personal business purposes (e.g. doctor, visit, etc.)

Note that all trips are modeled from home to non-home locations. This standard modeling practice is designated as modeling trips in "production-attraction" format. Trips from the non-home location to the home location are modeled as being made in the home to non-home direction. This convention allows for the consideration of household characteristics of trip-makers at their home (production) zone.

The BPM-V3 also includes intraregional models for the San Francisco Metropolitan Transportation Commission (MTC) and Southern California Association of Governments (SCAG) regions since high-speed rail may be an option for trips within those regions. Short-distance trips (less than 50 miles in length) that take place within the SCAG or MTC regions are modeled with separate intraregional mode choice models. Although these trips are not a major market for HSR, they are evaluated to get a more complete picture of travel within the state that may be attracted to and served by the HSR system. Both the SCAG and MTC intraregional mode choice models are based on a refined version of the MTC BAYCAST model. The models use static trip tables adopted from the SCAG and MTC regional models.[6] In addition, the models use transportation level of service (LOS) characteristics and household characteristics developed specifically for the HSR model system. During application, the models are run for all trips (both less than and greater than 50 miles in length), and then the long-distance trips (greater than or equal to 50 miles in length) are removed from the results (since they are modeled using the BPM-V3 long distance travel model). Thus, the model results presented in this section encompass all trip lengths without duplication.

1.1.2 Risk Analysis

A detailed, eight-step risk analysis approach was employed to forecast a range of revenue and ridership forecasts for the 2016 Business Plan as shown in Figure 1.2 below.[7] The process was used to forecast the probabilities of achieving different levels of ridership and revenue for the system based on the variation of specified risk factors that would affect future travel. The risk factors included calibrated model parameters as well as variation in input assumptions as shown in Table 1.1.

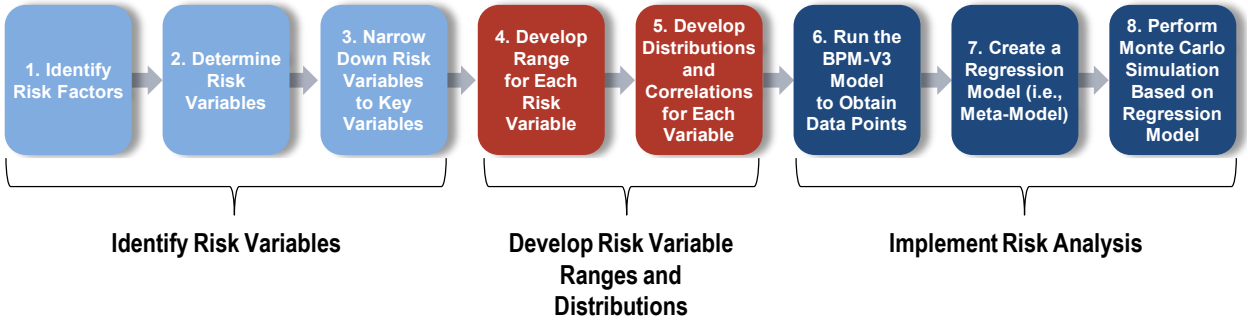
The key to the risk analysis approach was the development of simplified meta-models based on the specified risk factors that reasonably reproduced the results of the BPM-V3. The BPM-V3, which takes hours of computer time for each forecast, was run 59 times for each forecast year varying the risk factors. The resulting forecasts formed the inputs necessary for the development of linear regression-based models of the BPM-V3 forecasts that could be run in fractions of a second on a computer. This approach made it possible

[6] Southern California Association of Governments, *SCAG Regional Travel Demand Model and 2008 Model Validation*, June 2012; and Metropolitan Transportation Commission, *Travel Model Development: Calibration and Validation*, May 2012.

[7] See the 2016 Business Plan documentation for additional details regarding the risk analysis.

to produce 50,000 forecasts of ridership and revenue for each forecast year using Monte Carlo simulation procedures varying the input risk variables.

Figure 1.2 Risk Analysis Approach



Source: Cambridge Systematics.

Table 1.1 Risk Factors Considered by Forecast Year

Risk Variable	2025	2029	2040
HSR mode choice constant	x	x	x
Business/Commute and Recreation/Other trip frequency constants	x	x	x
Auto operating cost	x	x	x
HSR fares	x	x	x
HSR frequency of service	x	x	x
Availability and frequency of service of CVR and HSR bus connections to HSR termini	x		
Coefficient on transit access and egress TIME/AUTO DISTANCE variable	x	x	
Airfares		x	
Number and distribution of households throughout the state			x
Auto travel time			x

Source: Cambridge Systematics.

For business planning purposes, the 25th percentile forecast of HSR revenue was used; and for environmental analyses, the 75th percentile of HSR ridership was used. Since the risk analysis procedures produced only the HSR ridership or revenue forecasts, a separate, full, BPM-V3 forecast was performed with input values and assumptions set to reproduce the 75th percentile HSR ridership forecast. Estimation of 75th percentile VMT and VHT were based on this special forecast.

1.1.3 Modeling Process for Ridership and Differences in VMT

Two travel forecasts are produced for each forecast year in order to estimate differences in travel by each mode:

- a no-build forecast without the HSR system, and
- a build forecast with the HSR system.

The transportation systems and levels of service for auto, air, and CVR are assumed to be the same for the no-build and build forecasts.

Each of the model runs produces person trip tables for auto, air, CVR, and HSR for each of the four trip purposes. The BPM-V3 does not include a traffic assignment process since its primary focus was the forecast of HSR ridership and revenue. The California Statewide Travel Demand Model (CSTDM) does include a roadway network and traffic assignment process.[8] The BPM-V3 forecasts of person trips made by auto were, thus, processed using CSTDM forecast results to convert the auto person trips in the 50 or more mile range to auto vehicle trips. These were combined with CSTDM forecasts of auto vehicle trips less than 50 miles in length, commercial vehicle trips, and auto trips to, from, or through California and assigned to the CSTDM roadway network to produce VMT and VHT forecasts. Finally, since the BPM-V3 intraregional modeling procedures for the MTC and SCAG regions produced auto vehicle trips that can be assigned to the more detailed roadway networks in those regions, the intraregional VMT and VHT for those regions were used to replace the results of the CSTDM forecasts.

Detailed Procedures for Producing Differences in VMT

The BPM-V3 outputs auto person trips by four purposes – business, commute, recreation, and other. The CSTDM assignment process requires auto vehicle trips for the four different time periods – AM, midday, PM and off-peak for each of three different modes – single occupant vehicles (SOV), two occupant vehicles (HOV2), and three or more occupant vehicles (HOV3+). The following process was used to convert the BPM-V3 forecasts of auto person trips by purpose to vehicle trips by occupancy:

- BPM-V3 forecasts of auto person trips for business, commute, recreation, and other trip purposes were aggregated at the TAZ to TAZ level and then converted from production-attraction format to origin-destination format;
- The BPM-V3 auto person trips were split into short-distance (SD) trips greater than or equal to 50 miles and less than 100 miles and long-distance (LD) trips greater than or equal to 100 miles. The 100-mile cutoff distance was based on the CSTDM criterion of using straight line distance. The two trip tables were then converted from BPM-V3 zone system to CSTDM zone system based on proportion of area overlap;
- The total auto person trips were then split into person trips for the three different occupancy levels by the four time periods based on forecast CSTDM county to county proportions for each of the 12 combinations of person trips by vehicle occupancy by time of day. This step was performed for both for SD and LD trips.
- The person trips were then converted to vehicle trips by dividing the person trips by the occupancy level and summing the resulting vehicle trips. The CSTDM uses an HOV3+ occupancy rate of 3.6 persons per vehicle.
- CSTDM SD trips less than 50 miles (straight line distance) were added to the BPM-V3 SD trip table produce a full set of SD trips between 0-100 miles in length.

[8] Auto travel times used for the BPM-V3 are obtained from CSTDM forecasts.

- The resulting SD and LD vehicle trips were combined with commercial and external vehicle trips obtained from the CSTDM forecast for the appropriate year.

The resulting trip tables were then assigned for each of the four different time periods, and the resulting VMT on each link for each time of day was aggregated to produce statewide VMT estimate.

The above process was performed for both the no-build and 75th percentile BPM-V3 forecasts and the differences between the forecasts were calculated.

1.1.4 Process to Estimate Differences in Air Travel and Air Service Needs

As noted in Section 1.1.1, the introduction of HSR will divert trips from auto, air, and CVR. Those diverted trips can be consistently and deterministically forecast by comparing the differences in forecast trips by mode between the build and no-build alternatives.

The determination of changes in air service needs are more difficult to estimate since the amount of air service provided by carriers is based on their individual responses to HSR and other factors. Based on the structure of the BPM-V3, air trip interchanges can be assigned to origin and destination airports.[9] The average daily air passenger trips were multiplied by 365 to estimate annual intra-California air passenger trips. Each airport was assigned to one of six regions: San Francisco Bay Area, Sacramento Valley, San Diego, San Joaquin Valley, Southern California, and the Remainder of the state. The forecast no-build and modeled annual air trips were aggregated into tables of trips from airport region to airport region.

Annual passenger and flight data between California airports updated in May 2015 by the US Bureau of Transportation Statistics (BTS) were used to determine load factors for flights from each of the six regions. The detail of the BTS data allowed for the calculation of different load factors for flights internal to California and flights destined to locations outside of California.

The forecast airport region to airport region trips were then divided by the BTS derived load factor for the departure airport region to determine the number of annual flights required to serve the passenger loads based on load factors estimated from 2015 passenger and flight data. The reduction was then the estimated flights for the no-build forecast minus the estimated flights for the build forecast.

Flight reductions computed using the above approach represent what might be expected in the future. However, airline response to changes in air passengers due to the introduction of HSR might be different.

1.1.5 Greenhouse Gas Emissions Modeling

Authority analysts evaluated on-road vehicle emissions using average daily VMT estimates and associated average daily speed estimates for each affected county. Analysts estimated emission factors using the emission factors using the California Air Resources Board (CARB) emission factor program, EMission FACtors 2014 (EMFAC2014), which accounts for existing regulations that would reduce emissions, such as the Pavley Clean Car Standards. Parameters were set in the program for each individual county to reflect conditions within each county and statewide parameters to reflect travel through each county. The analysis was conducted for the following modeling years:

[9] Air passenger trips are in production-attraction format. Thus, the trips from airport A to airport B actually represent both the outbound and return trips to locations served by airport A.

- Existing (Year 2015)
- Opening Year (Year 2029)
- Horizon Year (Year 2040)

To determine overall pollutant burdens generated by on-road vehicles, analysts multiplied the estimated VMT by the applicable pollutant's emission factors, which are based on speed, vehicle mix, and analysis year.

Air-passenger trip reductions are the number of passengers that shift from air travel to the HSR system. Air-passenger trips are used to estimate the number of airplane flights reduced which results in airline fuel use reductions. Airplane flights removed are based on a full airplane cycle, including taxi/idle, take-off, climbing, cruise, decent, and landing. Emission factors are provided by airplane type and for each component of the full airplane cycle. The source of emissions factors for airplane flights include the Federal Aviation Administration's Aviation Environmental Design Tool (AEDT) and the California Air Resources Board (California 2000-2014 GHG Emission Inventory: Technical Support Document, 2016 Edition. September 2016).

1.2 Growth Forecasts

As documented in Section 1.1, the BPM-V3 is a choice model with four distinct steps: trip frequency choice, trip destination choice, main mode choice, and access/egress mode choice. The primary keys to growth in travel are the growth in the number of households and the amount of employment within California coupled with changes in accessibility afforded by the HSR system. This information directly impacts the total numbers of trips forecast through the trip frequency model and the distribution of those trips within the state.

1.2.1 Population, Household, and Employment Forecasts

Forecasts of future population, households, and employment in California used as input to the BPM-V3 were based on county-level socioeconomic estimates and forecasts from many sources, including:

- **Federal agencies:** U.S. Census Bureau;
- **State agencies:** California Department of Finance (DOF) and the California Employment Development Department (EDD);
- **MPOs:** Metropolitan Transportation Commission (MTC), Sacramento Area Council of Governments (SACOG), San Diego Association of Governments (SANDAG), Southern California Association of Governments (SCAG), and the San Joaquin Valley MPOs;
- **Third Parties within California:** input data for the CSTDM, California Economic Forecast Project (CEF), Center for Continuing Study of the California Economy, University of California Los Angeles (UCLA – Anderson School), and University of Southern California (Price School).
- **Third Parties outside California:** Moody Analytics and Woods & Poole, Inc.

The data and forecasts from the various agencies were critically evaluated and processed to produce county-level forecasts of population, households, and employment throughout the state. Information from the MPOs was used to disaggregate the forecasts to TAZs.

1.2.2 Growth in Trips Forecast by the Trip Frequency Model

The trip frequency choice model forecasts the choice of making either zero or one long distance trip greater than 50 miles by residents of California. The models produce the probabilities of a single person in each household type in a TAZ making one travel-alone long-distance trip and one travel-in-group long-distance trip on a given day. Household types are stratified by four household size groups (1, 2, 3, or 4+), three income groups (low, medium, or high income), three auto ownership groups (0, 1, or 2+ autos), and three number of workers groups (0, 1, or 2+ workers) to produce the numbers of households by each of 99 different household types for each TAZ.[10] The forecasts produce the probabilities of making either a production-attraction trip or the return attraction-production trip. The resulting probabilities represent the trips per person for each household type. The trips per person were multiplied by the household size and, then, by the number of households in the specific household size group to estimate the total person trips "generated." Thus, the growth in total forecast trips for any forecast year is directly related to the growth in the numbers of households by household type.

The forecast of future trips is also directly related to change in accessibility in the state. As roadways become more congested and travel times increase, accessibility decreases and, thus, long distance trips also decrease. Likewise, if the aggregate accessibility from a TAZ to all other TAZs increases due to good HSR connections, long distance trips from that TAZ will increase. When comparing a build alternative to a no-build alternative, an increase in total trip making for the build alternative can be considered one component of induced travel.

1.2.3 Growth in Corridor-Level Trips Forecast by the Destination Choice Model

The total numbers of trips produced by household in each TAZ are determined using the Trip Frequency model. However, based on changes in the accessibility for each TAZ to TAZ interchange, trips from a TAZ may be diverted from less accessible destination TAZs to more accessible destination TAZs. Thus, in comparison to a no-build alternative, trips between TAZs in well-served corridors may increase, compensating for decreases in trips in less well-served corridors. This change in trips due to accessibility constitutes as second component of induced travel.

1.3 Transportation Network

1.3.1 HSR Network Assumptions for the Different Horizon Years

The business case evaluation assumes that the high-speed rail project will open in phases, from 2025 through 2029, as described below.

Silicon Valley to Central Valley Line–Open in 2025

The Silicon Valley to Central Valley line is planned to begin service in 2025, characterized by:

- A north terminal at San Jose and a south terminal at a station north of Bakersfield (Figure 1.3);

[10] 4×3×3×3=108 household strata. However, nine illogical strata where number of workers per household are greater than the household size are removed.

- Dedicated coach services will be provided between the Fresno station and the Sacramento region, as well as between the line's southern terminus and locations in the Los Angeles Basin (LA Basin);
- Connections with Amtrak at Fresno to the Bay Area and Sacramento would be coordinated; and
- Potential extensions to the Silicon Valley to Central Valley phase would extend high-speed rail service from San Jose to San Francisco in the north and from the assumed southern terminus to Bakersfield.

Figure 1.3 Silicon Valley to Central Valley Line

Phase 1

Scheduled to start operations in 2029, Phase 1 completes the high-speed rail system from a north terminal at San Francisco to the south terminal at Anaheim (Figure 1.4), with these characteristics:

- High-speed rail service will operate on Caltrain tracks from San Jose to San Francisco, meaning that congestion on the corridor is taken into account for assumed travel time;
- Dedicated coach services would be provided from Merced to Sacramento;
- Connections with Amtrak at Merced to the Bay Area and Sacramento would be coordinated; and
- Connections with Metrolink feeder service at Los Angeles Union Station (LAUS) to LA Basin destinations would be coordinated.

Figure 1.4 Phase 1–Open in 2029

High-Speed Rail Service Plan Assumptions

High-speed rail fares for all 2016 Business Plan scenarios were identical to those in the 2014 Business Plan escalated from 2013 dollars to 2015 dollars. The fares are based on the formula below, with an $89 maximum in 2015 dollars:

- $32.26 + $0.1994 per mile (in 2015 dollars) for interregional fares;
- $23.94 + $0.1662 per mile (in 2015 dollars) for intraregional fares for the SCAG region; and
- $15.51 + $0.1330 per mile (in 2015 dollars) for intraregional fares for MTC and SANDAG regions.

Service assumptions varied by scenario. The details of the service frequencies are described in Table 1.2.

Table 1.2 High-Speed Rail Service Plan Assumptions by Scenario

Business Plan Scenario	North Terminus	South Terminus	High-Speed Rail Service Summary[a]	Dedicated Peak Bus Coach Connections[b]		Conventional Rail Connections
				North Terminus	South Terminus	
Silicon Valley to Central Valley Line	San Jose	North of Bakersfield	• 2 peak TPH from San Jose and North of Bakersfield (1 in off-peak)	• 2 peak BPH from Fresno and Sacramento (1 in off-peak)	• 2 BPH from North of Bakersfield and LAUS (1 in off-peak) • 2 BPH from North of Bakersfield and West LA (1 in off-peak) • 2 BPH from North of Bakersfield and Santa Anita (1 in off-peak)	• Coordinated service with Amtrak at Fresno
Silicon Valley to Central Valley Line Extension	San Francisco	Bakersfield	• 2 peak TPH from San Francisco and Bakersfield (1 in off-peak)	• 2 peak BPH from Fresno and Sacramento (1 in off-peak)	• 2 BPH from Bakersfield and LAUS (1 in off-peak) • 2 BPH from Bakersfield and West LA (1 in off-peak) • 2 BPH from Bakersfield and Santa Anita (1 in off-peak)	• Coordinated service with Amtrak at Fresno
Phase 1	San Francisco and Merced	Los Angeles and Anaheim	• 2 peak TPH from San Francisco and Los Angeles (3 in off-peak) • 2 peak TPH from San Francisco and Anaheim (1 in off-peak) • 2 peak TPH from San Jose and Los Angeles (0 in off-peak) • 1 peak TPH from Merced and Los Angeles (0 in off-peak) • 1 peak TPH from Merced and Anaheim (same in off-peak)	• 2 BPH from Sacramento and Merced (1 in off-peak)	None	• Coordinated service with Amtrak at Merced • Metrolink connections at LAUS

[a] TPH – Trains per Hour

[b] BPH - Buses per Hour

1.3.2 Assumed roadway improvements

The highway network assumptions were the same as those used for the CSTDM for each respective forecast year.[11] CS averaged AM and PM peak congested travel times derived from the CSTDM for use when peak travel times were needed in the mode choice model. Similarly, CS averaged midday and off-peak congested speeds for when off-peak travel times were needed. Auto terminal times representing the average time to access one's vehicle at each end of the trip were added to the congested travel time to get the total congested travel time skim. Terminal times were based on the area type and assessed at both the origin and destination of the trip. When the CSTDM forecast years did not match the 2016 Business Plan forecast years, the travel times for the modeled forecast years were determined by interpolating between the closest CSTDM forecast years.

Auto costs (besides operating costs) comprise tolls and parking costs. Toll costs were imported from networks developed for the CSTDM. Tolls corresponding to single-occupancy vehicles were assumed in the auto skims. Peak and off-peak tolls were averaged where costs differed. The parking costs developed for the 2010 base year scenario were used for all future year scenarios.

Automobile Operating Cost

Auto operating costs for the 2016 Business Plan were developed based on information regarding gasoline prices from the U.S. Energy Information Administration's (EIA) 2011 Annual Energy Outlook (AEO) coupled with projected motor gasoline prices in California based on the 2013 AEO, which extends through 2040. This procedure was consistent with the methodology used for the 2014 Business Plan. The forecasts for fuel efficiency were based on the adopted Corporate Average Fuel Economy (CAFE) standards for light-duty vehicles for model year 2012 to 2016, as well as fuel economy projections based on the 2013 AEO forecasts, which included the adopted fuel efficiency standards for model year 2017 through model year 2025. The auto operating costs used for the different forecast years are summarized in Table 1.3.

Table 1.3 Auto Operating Costs in 2015 Dollars

Forecast Year	Range (Cents per Mile)
2025	26
2029	26
2040	24

Source: Cambridge Systematics, Inc.

1.3.3 Aviation Network Assumptions

Air service assumptions for forecast years were based on the latest air service patterns in the California Corridor markets.[12] The past decade of U.S. Department of Transportation (DOT) data on airline service and fare levels were used to provide information on the economic factors affecting airline responses to changes

[11] For more information regarding the CSTDM model development and assumptions, see the documentation provided on the California DOT (Caltrans) web site: http://www.dot.ca.gov/hq/tsip/otfa/cstdm/cstdm_documentation.html.

[12] Forecasts were produced by Aviation System Consulting, LLC (ASC), a California-based expert firm.

in competition and capacity, and helped determine scenarios of potential airline competitive response to the introduction of high-speed rail service.

The baseline assumption for air fares and assumed headways for all forecast years was that air fares would remain consistent with average fares and frequency of service that were used in the 2014 Business Plan. Table 1.4 provides base airfares and headways between select major airports.

Table 1.4 Air Service Assumptions

Origin Airport	Destination Airport	Assumed Airfare (2015 Dollars)	Assumed Headway (Minutes)
Burbank	San Francisco	$115	480.0
Burbank	Sacramento	$112	150.0
Los Angeles	San Diego	$237	32.0
Los Angeles	San Francisco	$100	23.0
Oakland	San Diego	$111	46.0
Oakland	Los Angeles	$111	44.0
Sacramento	Burbank	$112	150.0
Sacramento	San Francisco	$299	141.0
San Francisco	San Diego	$96	28.0
San Francisco	Burbank	$115	480.0

Source: Aviation System Consulting.

1.3.4 Conventional Passenger Rail Service Assumptions

CVR service, including travel times, frequency of service, and stations served, were updated to reflect the latest conditions and forecasts from the 2013 California State Rail Plan (CSRP),[13] MPO forecasts, and the CSTDM. The largest service changes from 2016 conditions include increased conventional rail service on the Altamont Corridor Express and the San Joaquins to connect with HSR, and increased service between San Diego and Los Angeles via connected Coaster and Metrolink service. In the Silicon Valley to Central Valley scenarios, the enhanced San Joaquin trains were assumed to connect from Sacramento and Oakland to HSR at Fresno. In Phase 1, that connection was assumed to be at Merced. The sources for CVR service are summarized in Table 4.2 and operating frequencies are summarized in Table 4.3. Fare assumptions for all CVR lines were consistent with on-line published fares from 2011. Consistent with previous assumptions, the peak period was assumed to be three hours during each of the AM and PM peak periods, and 10 hours for the off-peak period.

2.0 Summary of Estimates

2.1 75th Percentile Travel Forecasts

2.1.1 Trips by Mode

2025 Results

Table 2.1 summarizes the annual trips by mode for the no-build and build alternatives for major markets in California in 2025. The results are raw model output and do not account for ramp-up. Table 2.2 summarizes the diversion of trips to HSR from other modes along with the induced long-distance travel. There are no forecast short distance changes in ridership in the MTC and SCAG regions for 2025 since the Silicon Valley to Central Valley HSR system does not serve those regions.

2029 Results

Table 2.3 summarizes the annual trips by mode for the no-build and build alternatives for major markets in California in 2025. The results are raw model output and do not account for ramp-up.

Table 2.4 summarizes the diversion of trips to HSR from other modes along with the induced long-distance travel. The short distance trip model for the MTC and SCAG regions was not rerun for the 2029 75th percentile no-build scenario. No-build trips by mode for 2029 were estimated by prorating the short distance HSR trips to the auto and CVR modes.

2040 Results

Table 2.5 summarizes the annual trips by mode for the no-build and build alternatives for major markets in California in 2025. The results are raw model output and do not account for ramp-up.

Table 2.6 summarizes the diversion of trips to HSR from other modes along with the induced long-distance travel. The short distance trip model for the MTC and SCAG regions was not rerun for the 2040 75th percentile no-build scenario. No-build trips by mode for 2040 were estimated by prorating the short distance HSR trips to the auto and CVR modes.

2.2 Changes in VMT

Table 2.7 and Table 2.8 summarize the assigned annual VMT in billions of miles and daily VMT in thousands of miles, respectively, for the three forecast years using the procedures outlined in Section 1.1.3. The modeling procedures used to forecast the assigned VMT are based on the underlying assumptions that the HSR system is operating in a steady state situation for the entire year.

Table 2.7 Annual Auto VMT in Billions of Miles

Summary	2025	2029	2040
Modeled Intraregional Assignment Results			
No-Build VMT	159.458	162.234	171.921
Build Alternative VMT	159.458	162.229	171.916
Change in VMT Due to HSR	0.000	-0.005	-0.005
Modeled Interregional Raw Assignment Results			
No-Build VMT	60.368	67.501	73.727
Build Alternative VMT	58.978	61.795	66.461
Change in VMT Due to HSR	-1.390	-5.706	-7.266
Modeled Total Raw Assignment Results			
No-Build VMT	219.826	229.735	245.648
Build Alternative VMT	218.436	224.024	238.377
Change in VMT Due to HSR	-1.390	-5.711	-7.271

2.3 Avoided Air Trips

Section 2.1.1 summarized the diversion of air passenger trips to HSR for the three forecast years. The procedures outlined in Section 1.1.4 were used to estimate the changes in required annual flights assuming airlines maintain the same passenger load factors achieved in 2015. Table 2.9 summarizes the results.

Table 2.9 Potential Annual Flight Reductions Due to Diversion of Air Trips to HSR

Scenario and Interchange	2025	2029	2040
No-Build			
Bay Area	97,058	93,895	137,732
Sacramento Valley	33,845	33,917	54,461
San Diego	31,976	31,714	48,483
San Joaquin Valley	3,544	2,553	6,097
Southern California	112,316	107,443	162,667
Rest of State	4,532	3,720	7,219
Total	283,270	273,240	416,659

2.4 Input to GHG analysis

Statewide VMT and Air-passenger trip reductions, calculated by the methodology discussed in 1.1.5 and expressed as metric tons of carbon dioxide equivalent, are combined and presented as the total GHG emissions avoided due to mode shift to high-speed rail service.

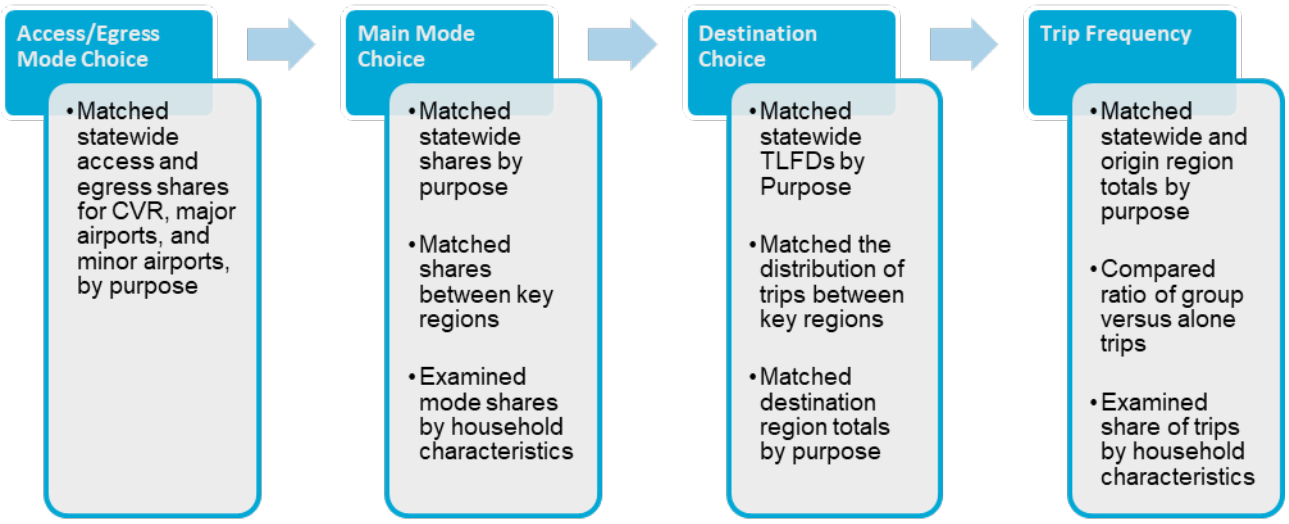
3.0 Model Calibration/Quality Control

3.1 BPM-V3 Calibration

The BPM-V3, including trip frequency, destination choice, main mode choice, and access/egress mode choice, was calibrated to reproduce estimates of long-distance travel patterns of California travelers.[14] The observed data were based on an expansion of the 2012-2013 CSHTS Daily Diary and Long-Distance survey data to match the socioeconomic characteristics of the 2010 California population.

Since the model components pass logsum information "up" through the modeling process and trip information "down" through the process, the individual model components had to be calibrated in an iterative fashion. The initial step was calibration of the access/egress portion of the mode choice model followed by, and sometimes simultaneously with, the main mode portion of the mode choice model. Once calibration targets were reached for access/egress and main mode choice models, destination choice was calibrated, followed by trip frequency. The process was repeated, since individual adjustments to one model could affect others. Figure 3-1 illustrates this iterative process used for calibration and targets for each model.

Figure 3-1 Calibration Process



Source: Cambridge Systematics.

3.2 Quality Control Measures

Ridership and revenue forecasts were based on information regarding the HSR service provided by the Rail Delivery Partners (RDP) and the Authority. Other input data were developed by CS such as auto, air, and CVR services and socioeconomic forecasts were reviewed with the RDP and Authority for reasonableness prior to being used in the BPM-V3. An internal quality control process was used to ensure that the correct data files were used for each run of the BPM-V3 and that the resulting forecasts were reasonable in comparison to other forecasts produced using the BPM-V3.

[14] Full details of the model calibration and validation process can be found in the BPM-V3 model documentation: https://www.hsr.ca.gov/docs/about/ridership/CHSR_Ridership_and_Revenue_Model_BP_Model_V3_Model_Doc.pdf

3.3 Peer Review Process

A formal Peer Review Panel (PRP) provided advice on the development, calibration, and validation of the BPM-V3. The following panelists comprised the PRP:

- Frank S. Koppelman, PhD, Professor Emeritus of Civil Engineering, Northwestern University (chair)
- Kay W. Axhausen, Dr.Ing., Professor, Institute for Transport Planning and Systems, ETH Zurich (Swiss Federal Institute of Technology Zurich)
- Eric Miller, PhD, Professor, Department of Civil Engineering, University of Toronto
- David Ory, PhD, Principal Planner/Analyst, Metropolitan Transportation Commission
- Kenneth A. Small, PhD, Professor Emeritus, Department of Economics, University of California-Irvine

The PRP was re-designated the Ridership Technical Advisory Panel (RTAP) in 2014 with the new designation stemming from the Authority's reliance on the PRP for advice rather than just reviews of completed work.

As stated in the 2016 Business Plan:[15]

> In their review of the forecasts and methodologies for this 2016 Business Plan, the Ridership Technical Advisory Panel (RTAP), a group of international experts in travel demand forecasting, stated that:
>
> > *"The review confirmed the Panel's previously expressed belief that the [Business Plan Model – Version 3] BPM-V3 model is suitable for use in business planning"*
> >
> > *"The Panel reviewed the Authority's design for a risk analysis for the 2016 Business Plan, as well as preliminary results on the likely range of ridership and revenue. This risk assessment is of high quality, more advanced than usual practice based on the Panel's experience, and highlights those uncertain factors that have a strong bearing on the results."*

The 2016 Business Plan ridership and revenue forecasts were also reviewed by Project Finance Advisory Limited (PFAL). In their memorandum to the Authority, PFAL stated:[16]

> *"We consider the CS forecasting model to be of good quality and can provide it with a clean bill of health in terms of its design and functionality. We have identified a number of areas where we consider the produced forecasts to be optimistic and also a number where we consider the forecasts to be pessimistic."*

[15] California High-Speed Rail Authority, *Connecting and Transforming California, 2016 Business Plan*, May 1, 2016, page 84.

[16] Memorandum from PFAL to Boris Lipkin, Deputy Director of Business, Analytics and Commercial Implementation, California High Speed Rail Authority, Re: HSR14-65 Draft Memo on Ridership and Revenue for Valley to Valley Line of the California High-Speed Rail System, dated December 5, 2016.

4.0 Uncertainty/Limitation

4.1 Focus on Differences in VMT Balances

"It's hard to make predictions, especially about the future."
Yogi Berra and others

The ridership and revenue forecasts are based on myriad predictions regarding the future including population, households and structure of those households, employment, the transportation system, travel costs, and traveler behavior. The potential for variation of some of the input variables has been rigorously taken into account through the formal risk analysis procedures documented in Section 1.1.2.

While there can be variation in the absolute magnitude of the ridership and revenue forecasts, some of the variation is reduced when alternatives are compared. The BPM-V3 is a deterministic model: If the same input assumptions are used for two different model runs, the same ridership and revenue forecasts will result. When two forecasts are compared, many of the inputs are the same. For the no-build and build forecasts, the only difference in the BPM-V3 inputs was the representation of the HSR system. As a result, there can be increased confidence in the veracity of the forecast differences.

4.2 Model Limitations

The BPM-V3, like any travel model, is based on a limited number of variables. While the BPM-V3 has been calibrated to reasonably reproduce travel for a base year, much of the "unexplained" variation in travel is "explained" through calibrated model constants. The constants account for unknown input variables that affect travel. In effect, the constants assume that the impacts of those unknown variables do not change over time.

The information and results presented in this technical memorandum are estimates and projections that involve subjective judgments, and may differ materially from the actual future ridership and revenue. This technical memorandum is not intended, nor shall it be construed, to constitute a guarantee, promise, or representation of any particular outcome(s) or result(s). Further, the material presented in this technical memorandum is provided solely for the Authority's planning purposes and should not be used for any other purpose.

4.3 Relevance for GHG estimation

The GHG analysis, as described earlier, was based on the calculation of VMT multiplied by an applicable pollutant's emission factor. Although the emission factors also consider vehicle speed, vehicle mix, and analysis year, the resultant GHG emission burdens are directly related to the VMT estimates. Since these VMT estimates are derived from the ridership and revenue forecasts, any limitations with regards to the certainty of the future ridership and revenue estimates also apply to the resultant GHG estimates. As such, the GHG estimates may differ from the actual future GHG emissions of the roadway network.

APPENDIX 3.2-C: TRAFFIC MITIGATION MEASURES SCREENING

1 INTRODUCTION

On February 5, 2021, the California High Speed Rail Authority (Authority) finalized "Decision-making Guidance for the Adoption of Traffic Mitigation Measures" (Authority 2021). This memorandum describes Senate Bill (SB) 743 and its effect on California Environmental Quality Act (CEQA) transportation analysis, describes National Environmental Policy Act (NEPA) requirements concerning the analysis of traffic effects and consideration of mitigation, and provides criteria for screening and selection of traffic mitigation. Five screening criteria were identified:

- The mitigation measure does not cause an increase in vehicle miles traveled (VMT).
- The measure would not contradict the objectives of SB 743.
- The measure is not more disruptive to the community than the traffic effect itself.
- The measure does not result in unmitigable secondary environmental effects.
- The California High-Speed Rail Authority (Authority) has determined the measure is practicable.

This appendix describes screening of traffic mitigation measures under consideration by the Authority as mitigation for traffic delays/congestion. A total of 44 potential site-specific traffic mitigation measures were reviewed in this screening analysis. Some of these measures would apply to all four project alternatives; some would only apply to one of the four alternatives. Eleven of the measures under consideration would not meet one or more of the screening criteria above, leaving 33 remaining measures which are included in Section 3.2, Transportation. The number of remaining measures varies by alternative, as discussed below.

2 SCREENING METHODOLOGY

The application and interpretation of the screening criteria are described below.

Increase in VMT

The Office of Planning and Research (OPR) (OPR 2018) has issued guidance in the evaluation of VMT, given its role in SB 743 implementation. The following is a description of project types that OPR indicates would generally lead to a measurable and substantial increase in vehicle travel/VMT.

- Addition of through lanes on existing or new highways, including general purpose lanes, high-occupancy vehicle (HOV) lanes, peak period lanes, auxiliary lanes, or lanes through grade-separated interchanges

OPR identifies a list of road projects, the most potentially relevant of which are listed below, that would not likely lead to a substantial or measurable increase in vehicle travel and therefore generally would not require an induced travel analysis.

- Addition of an auxiliary lane of less than 1 mile in length designed to improve roadway safety
- Addition of roadway capacity on local or collector streets provided the project also substantially improves conditions for pedestrians, cyclists, and, if applicable, transit
- Installation, removal, or reconfiguration of traffic control devices, including Transit Signal Priority (TSP) features
- Timing of signals to optimize vehicle, bicycle, or pedestrian flow
- Installation of traffic metering systems, detection systems, cameras, changeable message signs and other electronics designed to optimize vehicle, bicycle, or pedestrian flow
- Grade separation to separate vehicles from rail, transit, pedestrians, or bicycles or to replace a lane to separate preferential vehicles (e.g., HOV, HOT, or trucks) from general vehicles
- Installation of roundabouts or traffic circles
- Installation or reconfiguration of traffic calming devices
- Addition of new or enhanced bike or pedestrian facilities on existing streets/highways or within existing public rights-of-way

- Addition of Class I bike paths, trails, multi-use paths, or other off-road facilities that serve nonmotorized travel
- Rehabilitation, maintenance, replacement, safety, and repair projects designed to improve the condition of existing transportation assets

The National Center for Sustainable Transportation (NCST no date) provides an induced travel calculator that estimates the VMT induced annually because of adding vehicle travel lanes in any of California's urbanized counties. The annual induced VMT is calculated based on the facility type (freeway vs arterial), county location, and number of lane miles added.

In summary, the current mainstream view, articulated by OPR, is that mitigation measures that include signal timing modifications, installation of new traffic control devices, and/or turn lanes at intersections would not likely lead to a measurable increase in vehicle travel and VMT. Mitigation measures that add through lanes, either on freeway or arterial facilities, are likely to result in induced travel effects, particularly if the added travel lanes are through lanes of a mile or more in length.

While there are some differing opinions on this matter, the Authority has decided to rely on the written OPR guidance and follow the guidance of the state agency at the forefront of the consideration of VMT at this time.

Contradict the objectives of SB 743

The objectives of SB 743 are as follows:

- To promote the state's goals of reducing greenhouse gas (GHG) emissions and traffic-related air pollution,
- To promote the development of a multimodal transportation system,
- To provide clean, efficient access to destinations,
- To address the environmental impacts of traffic, such as noise, air pollution, and safety
- To balance congestion management with statewide goals related to infill development (diversity of land uses), promotion of public health through active transportation.

This screening evaluation considered a mitigation measure to not pass screening for the SB 743 criterion if it contradicted a SB 743 objective, as in it would make it more difficult to achieve the objectives due to some physical or operational hindrance.

- *GHG emissions and air pollution*: SB 743 identifies that reducing VMT will result in reducing GHG emissions and air pollution. Thus, a mitigation measure will be considered to contradict SB 743 if it substantially increases VMT. Since all the traffic mitigation measures will reduce traffic delay at intersections, if they do not substantially increase VMT, they would lower localized emissions (such as carbon monoxide) at congested intersections.
- *Multimodal transportation system*: Traffic mitigation measures, by definition, are addressing onroad vehicle congestion/delay, and onroad travel is dominated by private passenger vehicles. Thus, the primary beneficiary of traffic mitigation measures are private passenger vehicles, but bus transit will also benefit where transit crosses an intersection addressed by mitigation. None of the traffic mitigation measures under consideration would block or impede bus, rail, pedestrian, or bicycle modes of travel; they can all be designed to accommodate existing bike lanes, sidewalks, or bus stops. As such, they will not hinder the operation of a multi-modal system or block the completion of future multi-modal investments. As such, none of the measures currently under consideration are considered to contradict this objective.
- *Clean, efficient access to destinations*: Passenger cars are the dominant mode of travel in the project corridor. While there are plans to expand some transit systems (including the BART system and the potential increase of Caltrain service to Gilroy), the corridor between San Jose and Gilroy does not have efficient transit systems today, as reflected by the low mode share of transit in general. As a result, passenger vehicles are the most efficient mode of travel at present and likely for some time. As

to the "clean" criterion, transit modes are much cleaner on a passenger mile basis than personal vehicles, on average. However, none of the traffic mitigation measures under consideration would block or impede bus, rail, pedestrian, or bicycle modes of travel; as such, they will not hinder the operation of clean, efficient transit at present or block the development of such modes in the future. As such, none of the measures currently under consideration are considered to contradict this objective.

- *Noise, air pollution, and safety*: Air pollution was addressed in the first subcriteria above. SB 743 does not state that one of its purposes is to reduce noise or improve safety. Instead, it states that switching from level of service (LOS) to VMT does not relieve a lead agency from still addressing noise or safety associated with increases in traffic. As such, noise and safety have not been used as a SB 743 consistency criteria for this evaluation.
- *Infill development*: Traffic mitigation supports all development but is not targeted at infill especially. It is possible that traffic mitigation measures may help residents infill areas in downtown Gilroy and downtown San Jose, when they drive, to get in and out of their infill developments better. None of the traffic mitigation measures under consideration would block or otherwise impede infill development. As such, none of the measures currently under consideration are considered to contradict this objective.
- *Promotion of public health through active transportation:* Traffic mitigation measures do not promote active transportation such as biking or walking. However, all the traffic mitigation measures under consideration can be designed to accommodate existing bike lanes and sidewalks. As such, none of the measures currently under consideration are considered to contradict this objective.

More disruptive than the traffic effect itself

Evaluation under this criterion requires comparison of the effects of implementing a mitigation measure, which may include residential or business displacement, conversion of prime farmland or other effects, against the benefits of reducing traffic congestion/delay. This requires a comparison of different types of effects, which is not readily reduced to an objective quantitative comparison. As a result, there is inevitably some level of subjective judgement in completing screening against this criterion. Nevertheless, the evaluation of the mitigation measures regarding this criterion was conducted as follows:

- The traffic benefits of the measures were identified by identifying the highest traffic delay reduction during a peak period provided by the measure. The number of people exposed to the delay were identified by the PM peak total intersection volume.
- The secondary effects were identified by identifying first whether the measure could be completed in the existing road right-of-way or not. If it could not, then the effects of acquisition of right-of-way were evaluated by reviewing whether biological habitat, built environment historic sites, residences, business structures, important farmland, or publicly owned parks, recreational areas, or wildlife refuges were present. Operational effects considered included generation of VMT (which is also used as a proxy for operational air pollution, GHG emissions, and energy) and noise.
- Temporary effects during construction were not considered to be more disruptive than permanent traffic delays that are more than the adverse criteria used in the EIR/EIS.
- Permanent effects that could be resolved by mitigation were not considered to be more disruptive than permanent traffic delays that are more than the adverse criteria used in the EIR/EIS.
- Permanent effects that cannot be resolved by mitigation were considered to be more disruptive than permanent traffic delay effects that are less than 30 seconds.
- If the traffic delay reduction benefits are more than 30 seconds of intersection delay, this was considered to outweigh the identified permanent secondary effects identified in this evaluation.

Unmitigable secondary environmental effects

"Unmitigable" effects are defined in three different ways for this evaluation: (1) if the measure would result in a significant unavoidable impact under CEQA (such as conversion of prime farmland); (2) if the

measure would result in adverse effects that cannot be avoided under NEPA (such as operational noise) that would be considered adverse even after the adoption of other measures to reduce the secondary effects, and/or (3) if the measure would contribute to previously identified disproportionately high and adverse effects on minority populations or low-income populations.

The focus in this evaluation is on permanent effects, not temporary effects that may occur during the construction of site-specific traffic measures.

Payment for property acquisition and relocation assistance will be provided per state and federal requirements. Where there is adequate local availability for residential and/or commercial relocation within the same community, displacement is considered a “mitigable” effect. Where there is not adequate availability, displacement is considered an “unmitigable” effect.

Practicable

Practicability was defined in terms of technical, logistical, and financial feasibility. Logistical feasibility includes whether the measure is within the defined responsibilities and mission of the Authority.

3 SCREENING RESULTS BY CRITERION

The site-specific traffic mitigation measures under consideration are shown in Table 3.2-1, including identification of the location of impacts addressed, whether they are in an environmental justice community, a description of the measure, identification of which alternatives the mitigation applies to, the PM peak intersection traffic volumes, the traffic delay effects of the different alternatives, and the traffic benefits of the mitigation in terms of reduced delay.

The screening evaluation and results are summarized below. Table 3.2-2 presents the details of the evaluation including description of the secondary effects, whether additional right-of-way is required, whether the additional right-of-way acquisition would likely result in displacement of residences or businesses, whether the measure has additional effect on top of the project alternatives. Table 3.2-2 also identifies whether the measure would increase VMT, contradict the objectives of SB 743, have an unmitigable secondary effect, be more disruptive than the traffic effect, whether it would pass the four screening criteria. Table 3.2-2 also identifies whether the measure would reduce emergency vehicle response times (based on the analysis in Section 3.11, Safety and Security), but emergency vehicle response time was only considered in this evaluation if the traffic measure would reduce peak hour delays by more than 30 seconds (which is the adverse effect criteria used in Section 3.11).

Increase in VMT

Following OPR guidance, traffic measures improvements that do not include widening of roadways between crossing streets are not considered to result in a substantial increase in VMT. Three measures, one involving widening of U.S. Highway (US) 101 and two that would involve widening of Monterey Road, are considered to result in a substantial increase in VMT and would not meet this criterion.

Contradict the objectives of SB 743

Apart from the three mitigation measures that are considered to result in a substantial increase in VMT, none of the other measures are considered to contradict SB 743 objectives for the reasons discussed above in the discussion of methodology.

More disruptive to the community than the traffic effect itself

No biological habitat, built environment historic sites or publicly owned parks, recreational areas, or wildlife refuges were identified within the likely footprint of any of the traffic mitigation measures for intersection impacts. Some of the measures would include the acquisition of residential or commercial land, and some would likely result in displacement of residences or commercial businesses. Some of the displacements would occur in areas where relocation can occur within the same jurisdictions and some would not. Most of the traffic mitigation measures would occur within census districts where the percentage of minority persons or percentage of low-income persons is greater than the reference community (e.g., environmental justice communities) but a few would not.

Nine mitigation measures were identified as resulting in secondary effects that are more disruptive to the community than the traffic effect itself and thus would not meet this criterion. The secondary effects that outweighed the traffic benefits of the measures were the displacement of residences or businesses in an environmental justice community where there is insufficient availability to relocate them within the same local environmental justice community.

Unmitigable secondary environmental effects

Seven mitigation measures were identified as resulting in unmitigable secondary effects. These unmitigable effects included conversion of prime farmland/farmland of state importance and displacement of residential and/or commercial businesses where there is insufficient availability to relocate the residence or business within the same jurisdiction.

Practicability

Many of the measures are standard local intersection improvements and are considered practicable to implement. However, due to the substantial cost and high level of disruption and right-of-way needs, expanding US 101 and grade separations are not considered financially or institutionally practicable for implementation by the Authority given its defined responsibilities and mission.

4 OVERALL RESULTS AND RECOMMENDATIONS

Eleven out of 44 traffic mitigation measures would fail one or more of the first four of the screening criteria using the methodology described above, which would leave 33 remaining measures. These eleven measures are as follows:

Alternatives 1, 2, and 3:

- TR-MM#X.1: US 101 Corridor Mobility Improvements—Fair Share Contribution
- TR-MM#X.2: Coleman Avenue/Hedding Street—Widen and Reconfigure Eastbound Approach
- TR-MM#X.3: Coleman Avenue/Taylor Street—Widen and Reconfigure Southbound Approach
- TR-MM#X.4: Delmas Avenue/West San Fernando Street—Add Eastbound and Westbound Left Turn Lanes
- TR-MM#X.5: Autumn Street/West Fernando Street—Provide Eastbound and Westbound Left Turn Lanes
- TR-MM#X.6: Montgomery Street/Park Avenue: Reconfigure Northbound and Eastbound Approaches

Alternative 2 only:

- TR-MM#X.10: Monterey Road/Buena Vista Avenue

Alternative 4:

- TR-MM#X.7: Monterey Road/Masten Avenue
- TR-MM#X.8: Monterey Road/East Main Avenue—Widen and Reconfigure Westbound Approach
- TR MM #X.9: Depot Road/San Martin Avenue—Widen and Reconfigure Westbound Approach
- TR MM #X.11: Monterey Road/Leavesley Road —Widen and Reconfigure Eastbound Approach and Southbound Approach

The overall results of the screening are as follows (the remaining measures are shown in Table 3.2-2):

- Alternatives 1:
  - Total of 29 measures considered
  - 6 measures excluded
  - 23 measures remaining

- Alternative 2:
  - Total of 33 measures considered
  - 7 measures excluded
  - 26 measures remaining
- Alternative 3:
  - Total of 28 measures considered
  - 6 measures excluded
  - 22 measures remaining
- Alternative 4
  - Total of 17 measures considered
  - 5 measures excluded
  - 12 measures remaining

(if same) or Alt. 1	Delay (person-hours/day)	Traffic Delay Alt. 2 (if diff)	MM Benefit Alt. 2 (if Diff)	Traffic Delay Alt. 4 (if diff)	MM Benefit Alt. 4 (if Diff)
TR MM#1m: Lean Avenue/Blossom Hill Road – Improve Signal Phasing	M37	South San Jose	Yes	Modify the traffic signal phasing on the northbound and southbound approaches to Blossom Hill Road to replace the existing split phasing with protected left turn phasing.	X	X	X		1,970	26.3	-29.9	-33				
TR MM#1n: Cottle Road/Poughkeepsie Road – Restripe Eastbound Approach	M40	South San Jose	Yes	Restripe the intersection's eastbound Poughkeepsie Road approach to the Cottle Road intersection to provide an exclusive right turn lane. This would be accomplished by modifying the existing shared through-right turn lane to be an exclusive right turn lane	X	X	X		3,820	31.2	-31.1	-66				
TR-MM#1o: Santa Teresa Boulevard/Bernal Road—Restripe Westbound Approach	M17	South San Jose	Yes	Restripe the westbound approach at the Santa Teresa Boulevard/Bernal Road intersection, modify the westbound Bernal Road approach to convert a through lane to a left turn lane, and changes to the intersection's signal phasing.	X	X	X		3,930	16.7	-35.4	-77	16.7	-35.4		
TR-MM#1p: Santa Teresa Boulevard/Bailey Avenue—Reconfigure	M18	South San Jose	Yes	Reconfigure the Santa Teresa Boulevard/Bailey Avenue intersection. The specific improvements include the removal of the northbound and southbound channelized right turn pockets and their conversion to shared through-right lanes. Modifications to the existing traffic signal system at the intersection.	X	X	X		4,790	53.5	-61.9	-165	-296501			
TR-MM#1q: Monterey Road/Tilton Avenue—Various Improvements	M46	Morgan Hill	Yes	The mitigation for Alternatives 1 and 3 is the addition of a second eastbound right turn lane. Would require the elimination of on-street parking on the north side of Tilton Avenue approaching the intersection and narrowing of the landscaping on the south side of the roadway. Modifications to the traffic and rail signal systems at the intersection would also be necessary. The mitigation for Alternative 4 is the interconnection of the Monterey Road/Tilton Avenue intersection with the Monterey Road/Burnett Avenue intersection.	X		X	X	4,120 (Alt. 1) / 1,480 (Alt. 4)	52.5	-69.1	-158			19.2	-23.2

TR-MM#1r: Hale Avenue/Madrone Parkway—Signal at New Connection	M46	Morgan Hill	No	Alternative 2 alters the roadways and connections for Monterey Road/Tilton Avenue, and this intersection is replaced by a new connection at Hale Avenue/Madrone Parkway. The specific improvement as mitigation for Alternative 2 is the installation of a traffic signal at the new Hale Avenue/Madrone Parkway intersection.		X			2,370	114.5	-168.8	-222				
TR-MM#1s: Monterey Road/Madrone Parkway—Widen and Reconfigure	M47	Morgan Hill	Yes	Widen and reconfigure the Monterey Road/Madrone Parkway intersection. The specific improvements include reconfiguring the eastbound approach to include two right turn lanes and two left turn lanes and widening of the southbound approach to include a second southbound left turn lane		X			5,200	130.1	-101.4	-293				
TR MM #1t: Monterey Road/San Martin Avenue—Restripe Southbound Approach	MH6	San Martin	No	Restripe the southbound Monterey Road approach to provide additional capacity for the southbound left turn lane. This improvement would require the removal of the adjacent northbound left turn lane on Monterey Road into Burbank Avenue				X	490	12.1	NA	NA				
TR MM #1u: Monterey Road/IOOF Avenue—Widen and Reconfigure Southbound Approach	G25	Gilroy	Yes	Widen the southbound approach of Monterey Road to provide an additional southbound left pocket				X	3,458	126.7	-123.1	-236				
TR-MM#1v: Coordinate Signal Timings on 10th Street from Chestnut Street to Monterey Road in Gilroy	G36, G37, G38	Gilroy	Yes	Furnish and install signal interconnect equipment and coordinate all signals on 10th Street from Monterey Road to Chestnut Street. This improvement includes the intersections of 10th Street with Chestnut Street, Alexander Street, and Monterey Road	X	X			2,849/2,430/ 3,203	174.7	-170	-269	134.5	-130.5

TR-MM#X.1 US 101 Corridor Mobility Improvements—Fair Share Contribution	Freeway interchanges in South San Jose	South San Jose	Yes	Caltrans has identified future freeway widening and the construction of express lanes in the affected segments of US 101. These improvements would reduce the impact on freeway operations resulting from the project. While the improvements are included in the MTC RTP, they are not part of the implementation program funded for 2040. In concept, this measure would require the project to make a fair share contribution towards mobility improvements in the affected section of the highway corridor.	X	X	X		NA	NA	NA	NA				

Mitigation Measure	Intersection(s)	Community	EJ Community?	Detail	Alt. 1	Alt. 2	Alt. 3	Alt. 4	Traffic Volume (PM peak)	Traffic Delay all Alts. (if same) or Alt. 1.	MM Benefit All Alts. (if same) or Alt. 1	Delay (person-hours/day)	Traffic Delay Alt. 2 (if diff)	MM Benefit Alt. 2 (if Diff)	Traffic Delay Alt. 4 (if diff)	MM Benefit Alt. 4 (if Diff)
TR-MM#X.2: Coleman Avenue/Hedding Street—Widen and Reconfigure Eastbound Approach	D41	San Jose Diridon	Yes	Widen the eastbound Hedding Street approach to provide an additional left turn lane and an exclusive right turn lane, with the elimination of the existing channelized right turn. Modification to the traffic signal and removal of on-street parking on the south side of Hedding Street between Coleman Avenue and Chestnut Street.	X	X	X		8,720	6.8	-19.9	-96				
TR-MM#X.3: Coleman Avenue/Taylor Street—Widen and Reconfigure Southbound Approach	D42	San Jose Diridon	Yes	Widen the southbound Coleman Avenue approach to the Taylor Street intersection to include an exclusive right turn pocket and convert the existing shared through right to through-only lane. Modification to the traffic signal	X	X	X		8,218	5.3	-17.2	-79				
TR-MM#X.4: Delmas Avenue/West San Fernando Street—Add Eastbound and Westbound Left Turn Lanes	D44	San Jose Diridon	Yes	Modify the Delmas Avenue/West San Fernando Street intersection to provide exclusive eastbound and westbound (West San Fernando Street) left turn lanes. Modifications to the traffic signal at Delmas Avenue/West San Fernando Street intersection to accommodate the new movements and new protected phasing in the eastbound and westbound directions would also be necessary. Modifications to the adjacent VTA light rail crossing and signal system would be required.	X	X	X		1,543	13.7	-23.4	-20				
TR-MM#X.5: Autumn Street/West Fernando Street —Provide Eastbound and Westbound Left Turn Lanes	D25	San Jose Diridon	Yes	Modify the Autumn Street/West San Fernando Street intersection to provide exclusive eastbound and westbound (West San Fernando Street) left turn lanes and would apply to all project alternatives. This improvement would require the widening of West San Fernando Street and the acquisition of right-of-way from adjacent properties. Modifications to the traffic signal at Autumn Street/West San Fernando Street intersection to accommodate the new movements and new protected phasing in the eastbound and westbound directions would also be necessary.	X	X	X		3,246	8.5	NA	NA				

Mitigation Measure	Intersection(s)	Community	EJ Community?	Detail	Alt. 1	Alt. 2	Alt. 3	Alt. 4	Traffic Volume (PM peak)	Traffic Delay all Alts. (if same) or Alt. 1.	MM Benefit All Alts. TR-MM#X.6: Montgomery Street/Park Avenue: Reconfigure Northbound and Eastbound Approaches	D27	San Jose Diridon	Yes	Reconfigure the northbound and eastbound approaches to the intersection. This measure would reconfigure the northbound Montgomery Street approach to the Park Avenue intersection, removing the channelized right turn lane and restriping the northbound approach to provide two left turn pockets, one through lane and one shared through-right lane. This modification would also involve signal phasing changes, from the current north-south lead left phasing to a lead-lag phasing. This measure would also modify/restripe the eastbound lanes of Park Avenue at the Montgomery Street/Park Avenue intersection to provide two eastbound lanes on Park Avenue entering and departing the intersection. This measure would require the widening by restriping of the roadway to four lanes for 300 feet on either side of Montgomery Street, with standard transitions.	X	X	X		3,513	28.6	NA	NA				
TR-MM#X.7: Monterey Road/East Main Avenue—Widen and Reconfigure Westbound Approach	MH10	Morgan Hill	Yes	Widen the westbound East Main Avenue approach to provide an exclusive right turn lane and convert the shared through/right lane into a dedicated through lane. This improvement would require modification to the traffic signal, and the acquisition of right-of-way on the north side of East Main Street.				X	3,620	14.2	-78.3	-157				
TR MM #X.8: Depot Road/San Martin Avenue—Widen and Reconfigure Westbound Approach	MH7	San Martin	No	Widen the westbound San Martin Avenue approach to provide an additional westbound through lane. Removal of parking on the north side of San Martin Avenue				X	3,440	58.6	-73	-140				
TR-MM#X.9: Monterey Road/Masten Avenue	MH26	San Martin	No	Widen and reconfigure the Monterey Road/Masten Avenue intersection. The specific improvements include widening Masten Avenue to four lanes and widening Monterey Road to six lanes between Masten Avenue and Rucker Avenue.				X	1,170	53.6	NA	NA				
TR-MM#1l.10: Monterey Road/Buena Vista Avenue	G1	Gilroy	Yes	Widen and reconfigure the Monterey Road/Buena Vista Avenue intersection. The specific improvements include widening Monterey Road to six lanes between Buena Vista Avenue and Las Animas Avenue.		X			3,652	75.1	-75.5	-153				

Mitigation Measure	Intersection(s)	Community	EJ Community?	Detail	Alt. 1	Alt. 2	Alt. 3	Alt. 4	Traffic Volume (PM peak)	Traffic Delay all Alts. (if same) or Alt. 1.	MM Benefit All Alts. (if same) or Alt. 1	Delay (person-hours/day)	Traffic Delay Alt. 2 (if diff)	MM Benefit Alt. 2 (if Diff)	Traffic Delay Alt. 4 (if diff)	MM Benefit Alt. 4 (if Diff)
TR MM #X.11: Monterey Road/Leavesley Road — Widen and Reconfigure Eastbound Approach and Southbound Approach	G15	Gilroy	Yes	Widen the eastbound approach of Leavesley Avenue to provide a dedicated right turn pocket, and the southbound approach of Monterey Road to provide an additional southbound left pocket.				X	2,334	26.1	-14.9	-19				
TR-MM#X.12: Grade Separations	Multiple	San Jose, Morgan Hill, San Martin Gilroy	Yes	While grade separations are a technically feasible way to reduce traffic impacts at at-grade crossing locations, it is a highly expensive mitigation strategy and requires a collaborative approach of state, regional, and local agencies to fund and implement. The Authority would support future regional efforts for grade separation where acceptable to local communities and where federal, state, regional, and local funding can be obtained to fund these improvements. Table 3.2-2 Traffic Mitigation Measures Screening Evaluation, Part Two

Mitigation Measure	Intersection(s)	Community	Alt. 1	Alt. 2	Alt. 3	Alt. 4	Secondary Effect	Additional ROW?	Displacement?	More effect?	C1: Increase VMT?	C2: Contradict objectives of SB 743?	C3: More Disruptive than Traffic Effect?	C4: Unmitigable Secondary Effect?	C5: Practicable?	Pass Screening?
TR-MM#1a: Monterey Road Construction Modifications	Monterey Road intersections in SSJ	South San Jose	X	X	X		The improvements would occur entirely in the existing rights-of-way and the project footprint of the project alternatives	No	No	No	No	No. See text discussion.	No	No	Yes	Yes
TR-MM#1b: The Alameda (SR 82)/Taylor Street–Naglee Avenue—Restripe Northbound Approach	D4	San Jose Diridon	X	X	X		Removing curb on-street parking for the block between West Taylor Street and Naglee Avenue on the east side of The Alameda.	No	No	Yes	No	No. See text discussion.	No	No	Yes	Yes
TR-MM#1c: Optimize Signal Coordination on West Santa Clara Street from Stockton Street to Autumn Street in San Jose	D13, D14, D15	San Jose Diridon	X	X	X	X	All work would be accomplished in the existing roadway right-of-way.	No	No	No	No	No. See text discussion.	No	No	Yes	Yes
TR-MM#1d: Monterey Road/Capitol Expressway EB Ramps—Widen and Reconfigure	M2	South San Jose	X	X	X		This improvement would be accommodated within the existing roadway right-of-way.	No	No	No	No	No. See text discussion.	No	No	Yes	Yes
TR-MM#1e: Monterey Road/Chynoweth Avenue-Roeder Road—Widen and Reconfigure	M9	South San Jose	X	X	X	X	Right-of-way would need be acquired in the northeast and southeast corners of intersection, which are occupied by commercial establishments (reconfigure two gas stations pumps)	Yes	Yes (gas pumps)	Yes	No	No. See text discussion.	No	No Gas pumps can be relocated.	Yes	Yes
TR-MM#1f: Monterey Road/Senter Road—Widen and Reconfigure Southbound Approach	M3	South San Jose	X	X	X		Acquisition of right-of-way from the northeast corner of the intersection, which is occupied by commercial establishments Acquisition on gas station property; possibly reconfiguration of pumps and building and parking lot	Yes	Yes (gas pumps)	Yes	No	No. See text discussion.	No	No Gas pumps can be relocated.	Yes	Yes
TR-MM#1g: Monterey Road/Senter Road—Widen and Reconfigure Westbound Approach	M3	South San Jose	X	X	X		Acquisition of additional right-of-way in the northeast corner of the intersection, Acquisition on gas station property; possibly reconfiguration of pumps and building	Yes	Yes (gas pumps)	Yes	No	No. See text discussion.	No	No Gas pumps can be relocated.	Yes	Yes
TR-MM#1h: Monterey Road/Blossom Hill Westbound Ramps—Reconfigure Northbound Approach	M11, M23, M24	South San Jose	X	X	X		All work would be accomplished in the existing roadway right-of-way.	No	No	No	No	No. See text discussion.	No	No	Yes	Yes

Mitigation Measure	Intersection(s)	Community	Alt. 1	Alt. 2	Alt. 3	Alt. 4	Secondary Effect	Additional ROW?	Displacement?	More effect?	C1: Increase VMT?	C2: Contradict objectives of SB 743?	C3: More Disruptive than Traffic Effect?	C4: Unmitigable Secondary Effect?	C5: Practicable?	Pass Screening?
TR-MM#1i: Monterey Road/Blossom Hill Road Eastbound Ramps—Widen and Reconfigure	M12	South San Jose	X	X	X		Acquisition of additional right-of-way from the northeast corner of the intersection would be necessary. This parcel is currently unoccupied (middle of the SE interchange loop is ornamental woodland). No additional to Alt. 2 (because the IC is rebuilt with Alt. 2).	Yes	No	Yes	No	No. See text discussion.	No	No	Yes	Yes
TR-MM#1j: Senter Road/Hellyer Avenue—Restripe Westbound Approach	M30	South San Jose	X	X	X		All work would be accomplished in the existing roadway right-of-way.	No	No	No	No	No. See text discussion.	No	No	Yes	Yes
TR-MM#1k: Houndshaven Way/Skyway Drive—Widen and Reconfigure	M5	South San Jose	X	X	X		This would require acquisition of additional right-of-way from the parcel east of Monterey Road that is north of Skyway Drive, which is being procured as part of the project, so no additional displacement beyond the project	Yes	No additional beyond that included in the project.	Yes	No	No. See text discussion.	No	No	Yes	Yes
TR MM #1l: Vistapark/Branham Lane—Reconfigure Southbound Approach	M32	South San Jose	X	X	X		All work would be accomplished in the existing roadway right-of-way.	No	No	No	No	No. See text discussion.	No	No	Yes	Yes
TR MM#1m: Lean Avenue/Blossom Hill Road – Improve Signal Phasing	M37	South San Jose	X	X	X		All work would be accomplished in the existing roadway right-of-way.	No	No	No	No	No. See text discussion.	No	No	Yes	Yes
TR MM#1n: Cottle Road/Poughkeepsie Road – Restripe Eastbound Approach	M40	South San Jose	X	X	X		All work would be accomplished in the existing roadway right-of-way.	No	No	No	No	No. See text discussion.	No	No	Yes	Yes
TR-MM#1o: Santa Teresa Boulevard/Bernal Road—Restripe Westbound Approach	M17	South San Jose	X	X	X		All work would be accomplished in the existing roadway right-of-way.	No	No	No	No	No. See text discussion.	No	No	Yes	Yes
TR-MM#1p: Santa Teresa Boulevard/Bailey Avenue—Reconfigure	M18	South San Jose	X	X	X		This improvement could be accomplished entirely in the existing right-of-way.	No	No	Yes	No	No. See text discussion.	No	No	Yes	Yes

Mitigation Measure	Intersection(s)	Community	Alt. 1	Alt. 2	Alt. 3	Alt. 4	Secondary Effect	Additional ROW?	Displacement?	More effect?	C1: Increase VMT?	C2: Contradict objectives of SB 743?	C3: More Disruptive than Traffic Effect?	C4: Unmitigable Secondary Effect?	C5: Practicable?	Pass Screening?
TR-MM#1q: Monterey Road/Tilton Avenue—Various Improvements	M46	Morgan Hill	X		X	X	Alternatives 1/3: Elimination of on-street parking on the north side of Tilton Avenue approaching the intersection and narrowing of the landscaping on the south side of the roadway (residential) Modifications to the traffic and rail signal systems at the intersection. Alternative 4 would be accomplished within the roadway right-of-way.	Yes (Alt. 1, 3)	No	Yes	No	No. See text discussion.	No	No	Yes	Yes
TR-MM#1r: Hale Avenue/Madrone Parkway—Signal at New Connection	M46	Morgan Hill		X			Would be accomplished within the roadway right-of-way.	No	No	No	No	No. See text discussion.	No	No	Yes	Yes
TR-MM#1s: Monterey Road/Madrone Parkway—Widen and Reconfigure	M47	Morgan Hill		X			Would require a modification to the Alternative 2 roadway design modifications at this location and would be accommodated within the Alternative 2 footprint and right-of-way	No	No	No	No	No. See text discussion.	No	No	Yes	Yes
TR MM #1t: Monterey Road/San Martin Avenue—Restripe Southbound Approach	MH6	San Martin				X	All work would be accomplished in the existing roadway right-of-way but would result in the removal of vehicle capacity at an adjacent intersection (Monterey/Burbank)	No	No	Yes	No	No. See text discussion.	No	No	Yes	Yes
TR MM #1u: Monterey Road/IOOF Avenue—Widen and Reconfigure Southbound Approach	G25	Gilroy				X	Removal of parking on the west side of Monterey Road.	No	No	Yes	No	No. See text discussion.	No	No	Yes	Yes
TR-MM#1v: Coordinate Signal Timings on 10th Street from Chestnut Street to Monterey Road in Gilroy	G36, G37, G38	Gilroy	X	X			All work would be accomplished in the existing roadway right-of-way.	No	No	No	No	No. See text discussion.	No	No	Yes	Yes
TR MM #1w: Chestnut Street/Luchessa Ave—Reconfigure Southbound Approach	G60	Gilroy				X	All work would be accomplished in the existing roadway right-of-way.	No	No	No	No	No. See text discussion.	No	No	Yes	Yes
TR-MM#1x.1: Cahill Street/Stover-Crandall Street—Install Traffic Signal	D21	San Jose Diridon	X	X	X	X	All work would be accomplished in the existing roadway right-of-way.	No	No	No	No	No. See text discussion.	No	No	Yes	Yes

TR-MM#1x.4: Houndshaven Way/Skyway Drive—Install Traffic Signal	M5	South San Jose	X	X	X		All work would be accomplished in the existing roadway right-of-way.	No	No	No	No	No. See text discussion.	No	No	Yes	Yes
TR-MM#1x.5: Hale Avenue/Tilton Avenue—Install Traffic Signal	M19	Morgan Hill	X	X	X		All work would be accomplished in the existing roadway right-of-way.	No	No	No	No	No. See text discussion.	No	No	Yes	Yes
TR-MM#1x.6: East Main Avenue/Depot Street—Install Traffic Signal	MH11	Morgan Hill				X	All work would be accomplished in the existing roadway right-of-way.	No	No	No	No	No. See text discussion.	No	No	Yes	Yes
TR-MM#1x.7: Railroad Avenue/Tennant Avenue—Install Traffic Signal	MH2	Morgan Hill		X			All work would be accomplished in the existing roadway right-of-way.	No	No	No	No	No. See text discussion.	No	No	Yes	Yes
TR-MM#1x.8: Llagas Road/San Martin Avenue—Install Traffic Signal	MH8	San Martin		X			All work would be accomplished in the existing roadway right-of-way.	No	No	No	No	No. See text discussion.	No	No	Yes	Yes
TR-MM#1x.9: School Access/IOOF Avenue—Install Traffic Signal	G53	Gilroy				X	All work would be accomplished in the existing roadway right-of-way.	No	No	No	No	No. See text discussion.	No	No	Yes	Yes
TR-MM#1x.10: SR 25/Bloomfield—Install Traffic Signal	GM4	Gilroy	X	X	X	X	All work would be accomplished in the existing roadway right-of-way but there would be removal of parking on the west side of Monterey Road.	No	No	No	No	No. See text discussion.	No	No	Yes	Yes
TR-MM#X.1 US 101 Corridor Mobility Improvements - Fair Share Contribution	Freeway interchanges in South San Jose	South San Jose	X	X	X		Widening of the freeway and adding new freeway capacity would likely result in a substantial increase in VMT. Widening could also result in acquisition of right-of-way and displacements, construction disruption, traffic noise effects, biological resource effects, and other effects.	Likely	Potentially	Yes	Yes	Yes	Yes Widening of US 101 may be necessary for other regional movement needs but would be disproportionate to the project's traffic effects.	Yes While not analyzed in any detail, large-scale freeway widening usually results in some unmitigable effects.	No It is outside the Authority's mission and authority to fund freeway expansion.	No

Mitigation Measure	Intersection(s)	Community	Alt. 1	Alt. 2	Alt. 3	Alt. 4	Secondary Effect	Additional ROW?	Displacement?	More effect?	C1: Increase VMT?	C2: Contradict objectives of SB 743?	C3: More Disruptive than Traffic Effect?	C4: Unmitigable Secondary Effect?	C5: Practicable?	Pass Screening?
TR-MM#X.2: Coleman Avenue/Hedding Street—Widen and Reconfigure Eastbound Approach	D41	San Jose Diridon	X	X	X		Removal of on-street parking on the south side of Hedding Street between Coleman Avenue and Chestnut Street, and the acquisition of right-of-way on the south side of Hedding Street. Displace commercial building SE corner of Coleman/Hedding and displacement of 3 residences up to 300' from intersection	Yes	Yes (3 residential and 1 commercial) There is available residential and commercial relocation in San Jose.	Yes	No	No. See text discussion.	Yes Although there is available relocation in San Jose, relocation may not occur within EJ community. Also traffic delay effect (7 to 20 seconds) is limited.	No Primary effect is displacement, but there is available relocation availability in San Jose in general.	Yes	No
TR-MM#X.3: Coleman Avenue/Taylor Street—Widen and Reconfigure Southbound Approach	D42	San Jose Diridon	X	X	X		Widening of Coleman Avenue, which would require the acquisition of adjacent property on the west side of Coleman Avenue occupied by commercial establishments. Acquisition of parking and one displacement of commercial building	Yes	Yes (commercial) There is available commercial relocation in San Jose.	Yes	No	No. See text discussion.	Yes Although there is available relocation in San Jose, relocation may not occur within EJ community. Also traffic delay effect (5 to 17 seconds) is limited.	No Primary effect is displacement, but there is available relocation availability in San Jose in general.	Yes	No
TR-MM#X.4: Delmas Avenue/West San Fernando Street—Add Eastbound and Westbound Left Turn Lanes	D44	San Jose Diridon	X	X	X		Acquisition of adjacent property and changes to the adjacent VTA light rail crossing and signal system. Residential (5-7) and commercial building (1) displacement 300 feet on either side of the intersection.	Yes	Yes (5-7 residential and 1 commercial) There is available residential and commercial relocation in San Jose.	Yes	No	No. See text discussion.	Yes Although there is available relocation in San Jose, relocation may not occur within EJ community. In addition, unavoidable temporary disruption to VTA during construction. Also traffic delay effect (14 to 23 seconds) is limited.	No There is available relocation availability in San Jose in general.	Yes	No
TR-MM#X.5: Autumn Street/West Fernando Street—Provide Eastbound and Westbound Left Turn Lanes	D25	San Jose Diridon	X	X	X		The City of San Jose has recently narrowed Autumn Street by one northbound through lane and bike improvements (including bike lanes) have been made and West San Fernando Street has also been narrowed to include bike lanes. As a result, this measure would require adding back the through lanes and removing the bike lanes (which would be inconsistent with the City's road diet intent for this location) or acquisition of substantial adjacent property, which would result in commercial and/or residential displacements	Yes	Yes	Yes	No	No. See text discussion.	Yes. Although there is available relocation in San Jose, relocation may not occur within EJ community. Inconsistent with current City circulation planning. Also traffic delay effect (8 seconds) is limited.	No There is available relocation availability in San Jose in general.	Yes	No

Mitigation Measure	Intersection(s)	Community	Alt. 1	Alt. 2	Alt. 3	Alt. 4	Secondary Effect	Additional ROW?	Displacement?	More effect?	C1: Increase VMT?	C2: Contradict objectives of SB 743?	C3: More Disruptive than Traffic Effect?	C4: Unmitigable Secondary Effect?	C5: Practicable?	Pass Screening?
TR-MM#X.6: Montgomery Street/Park Avenue: Reconfigure Northbound and Eastbound Approaches	D27	San Jose Diridon	X	X	X		The City of San Jose has recently made improvements to the Montgomery Street/Park Avenue intersection. Northbound Montgomery was narrowed by one through lane to add in bike improvements. As a result, this measure would require adding back the through lane and removing the bike lanes, which would be inconsistent with the City's road diet intent for this location, or acquisition of substantial adjacent property, which would result in commercial and/or residential displacements.	Yes	Yes	Yes	No	No. See text discussion.	Yes Although there is available relocation in San Jose, relocation may not occur within EJ community. Inconsistent with current City circulation planning Also traffic delay effect (28 seconds) is limited.	No There is available relocation availability in San Jose in general.	Yes	No
TR-MM#X.7: Monterey Road/East Main Avenue—Widen and Reconfigure Westbound Approach	MH10	Morgan Hill				X	Acquisition of right-of-way on the north side of East Main Street. This right-of-way is currently occupied by commercial establishments.	Yes	Yes (commercial) There is insufficient commercial relocation availability in Gilroy with Alt. 4.	Yes	No	No. See text discussion.	Yes Would result in commercial displacement within EJ community and there is insufficient relocation availability in Gilroy. Also traffic delay effect (14 seconds) is limited.	Yes Would result in commercial displacement and there is insufficient commercial relocation availability in Gilroy.	Yes	No
TR MM #X.8: Depot Road/San Martin Avenue—Widen and Reconfigure Westbound Approach	MH7	San Martin				X	Acquisition of right-of-way and removal of parking on the north side of San Martin Avenue. The parcel is currently occupied by a commercial establishment and 2-3 residences	Yes	Yes (commercial and 2-3 residences) There is insufficient commercial relocation availability in San Martin.	Yes	No	No. See text discussion.	No Would result in commercial displacement and there is insufficient commercial relocation availability in San Martin, but the traffic effect is substantial (59 seconds per move and 140 person hours/day) and the MM would completely avoid the delay.	Yes Would result in commercial displacement and there is insufficient commercial relocation availability in San Martin.	Yes	No

Mitigation Measure	Intersection(s)	Community	Alt. 1	Alt. 2	Alt. 3	Alt. 4	Secondary Effect	Additional ROW?	Displacement?	More effect?	C1: Increase VMT?	C2: Contradict objectives of SB 743?	C3: More Disruptive than Traffic Effect?	C4: Unmitigable Secondary Effect?	C5: Practicable?	Pass Screening?
TR-MM#X.9: Monterey Road/Masten Avenue	MH26	San Martin				X	Would require the procurement of additional right-of-way along the north side or south side of Masten Avenue and on the west side of Monterey Road between Masten and Ricker. Along Masten, the area within 300 feet of the intersection is prime farmland or farmland of state importance on the south and vacant land on the north side. The area west of Monterey Road is prime farmland	Yes	No	Yes	Yes (0.43 mile increase from 4 to 6 lanes)	Yes Probably would not induce VMT on its own, but it would widen 0.43 miles of Monterey Road which could contribute to cumulative VMT inducement.	No	Yes While the amount of generated VMT would be far smaller than the VMT reduction due to HSR, the project would convert prime farmland/ farmland of state importance.	Yes	No
TR-MM#1l.10: Monterey Road/Buena Vista Avenue	G1	Gilroy		X			Right-of-way would need to be acquired on both sides of Monterey Road between Buena Vista Avenue and Las Animas Avenue. These parcels are occupied by agricultural, commercial, or residential uses. Widening to the west would require acquisition of prime farmland and farmland of state importance, commercial land, and residential property and may displace a number of residences.	Yes	Yes (residential) There is insufficient residential relocation in Gilroy with Alt. 2.	Yes	Yes (0.9 mile increase 4 to 6 lanes)	Yes Roadway widening is adjacent to development and could induce VMT	No. Would result in residential displacement without available relocation locally but the traffic effect is substantial (75 seconds per move, and 153 hours delay per day) and the MM would completely avoid the delay.	Yes While the amount of generated VMT would be far smaller than the VMT reduction due to HSR, there is insufficient residential relocation availability in Gilroy with Alt. 2. Would also convert prime farmland/farmland of state importance.	Yes	No
TR MM #X.11: Monterey Road/Leavesley Road —Widen and Reconfigure Eastbound Approach and Southbound Approach	G15	Gilroy				X	Right-of-way acquisition on the northwest and southwest corners of the intersection. These parcels are occupied by commercial establishments.	Yes	Yes (commercial) There is insufficient commercial relocation availability in Gilroy with Alt. 4.	Yes	No	No. See text discussion.	Yes Would result in commercial displacement within EJ community and insufficient local relocation availability in Gilroy.	Yes Would result in commercial displacement and there is insufficient commercial relocation availability in Gilroy.	Yes	No

Mitigation Measure	Intersection(s)	Community	Alt. 1	Alt. 2	Alt. 3	Alt. 4	Secondary Effect	Additional ROW?	Displacement?	More effect?	C1: Increase VMT?	C2: Contradict objectives of SB 743?	C3: More Disruptive than Traffic Effect?	C4: Unmitigable Secondary Effect?	C5: Practicable?	Pass Screening?
TR-MM#X.12: Grade Separations	Multiple	San Jose, Morgan Hill, San Martin Gilroy				X	Grade separations, depending on location and design can have substantial secondary environmental impacts, including construction disruption to roadways and rail operations as well as construction noise and air pollution emissions, visual aesthetic changes, right-of-way acquisition, displacement of residential and commercial development, encroachment on public parks and open space, removal of trees and vegetation, and impacts on groundwater. However, it is speculative to ascribe specific impacts absent detailed location and designs.	Yes	Yes	Yes	No	No. See text discussion.	Yes Would result in residential and commercial displacements within EJ communities and there is insufficient local relocation availability in certain locations. Construction disruption would be extensive.	Yes Would result in residential and commercial displacements within EJ communities and there is insufficient local relocation availability in certain locations. Construction disruption would be extensive.	No. While the Authority supports a regional effort to identify funding and implement crossing improvements, the Authority cannot commit to a comprehensive program of grade separations to address all significantly affected intersections because of funding limitations without jeopardizing the implementation of the project.	No

Alt. = alternative
Authority = California High-Speed Rail Authority
EB = eastbound
EJ = environmental justice
HSR = high-speed rail
IC = interchange
MM = mitigation measure
ROW = right-of-way
SB = southbound
SE = southeast
SR = State Route
SSJ = South San Jose
US = U.S. Highway
VMT = vehicle miles traveled
VTA = Santa Clara Valley Transportation Authority

APPENDIX 3.3-A: AIR QUALITY AND GREENHOUSE GASES TECHNICAL REPORT

California High-Speed Rail Authority

San Jose to Merced Project Section

Air Quality and Greenhouse Gases Technical Report

February 2022

CALIFORNIA High-Speed Rail Authority

The environmental review, consultation, and other actions required by applicable federal environmental laws for this project are being or have been carried out by the State of California pursuant to 23 U.S.C. 327 and a Memorandum of Understanding dated July 23, 2019, and executed by the Federal Railroad Administration and the State of California.

TABLE OF CONTENTS

EXECUTIVE SUMMARY XV

1 INTRODUCTION 1-1
1.1 Background of the HSR Program 1-2
1.2 Purpose of this Technical Report 1-2
1.3 Organization of this Technical Report 1-3

2 DESCRIPTION OF THE SAN JOSE TO CENTRAL VALLEY WYE PROJECT 2-1
2.1 Summary of Design Features 2-2
2.2 Description of Alternatives 2-10
2.2.1 Alternative 1 2-10
2.2.2 Alternative 2 2-25
2.2.3 Alternative 3 2-34
2.2.4 Alternative 4 (State's Preferred Alternative, CEQA Proposed Project) 2-42
2.3 Impact Avoidance and Minimization Features 2-53

3 LAWS, REGULATIONS, AND ORDERS 3-1
3.1 Federal 3-1
3.1.1 Clean Air Act (42 U.S.C. § 7401) and National Ambient Air Quality Standards 3-1
3.1.2 Conformity Rule 3-5
3.1.3 Mobile Source Air Toxics/Hazardous Air Pollutants 3-5
3.1.4 Federal Greenhouse Gas Regulations and Guidance 3-6
3.2 State 3-8
3.2.1 California Clean Air Act and California Ambient Air Quality Standards 3-8
3.2.2 Mobile Source Air Toxics/Toxic Air Contaminates 3-8
3.2.3 California Greenhouse Gas Regulations and Guidance 3-9
3.2.4 California Asbestos Control Measures 3-12
3.3 Regional and Local 3-12
3.3.1 Air Quality Management Districts 3-12
3.3.2 Metropolitan Transportation Commission 3-16
3.3.3 Association of Bay Area Governments 3-16
3.3.4 Association of Monterey Bay Area Governments 3-16
3.3.5 Council of San Benito County Governments 3-17
3.3.6 Merced County Association of Governments 3-17
3.3.7 Air Quality Plans 3-17
3.3.8 Climate Action Plans 3-26

4 POLLUTANTS OF CONCERN 4-1
4.1 Criteria Pollutants 4-1
4.1.1 Ozone 4-1
4.1.2 Particulate Matter 4-2
4.1.3 Carbon Monoxide 4-3
4.1.4 Nitrogen Dioxide 4-4
4.1.5 Lead 4-4
4.1.6 Sulfur Dioxide 4-4
4.2 Toxic and Noncriteria Pollutants 4-5
4.2.1 Asbestos 4-5

4.2.2 Mobile Source Air Toxics 4-5
4.3 Valley Fever 4-8
4.4 Greenhouse Gases 4-9

5 AFFECTED ENVIRONMENT 5-1
5.1 Meteorology and Climate 5-1
5.1.1 San Francisco Bay Area Air Basin (Santa Clara Valley Subregion) 5-1
5.1.2 North Central Coast Air Basin 5-1
5.1.3 San Joaquin Valley Air Basin 5-2
5.2 Ambient Air Quality 5-2
5.3 Attainment Status 5-3
5.4 Emissions Inventory 5-10
5.4.1 Criteria Pollutants 5-10
5.4.2 Statewide Greenhouse Gas Emissions 5-12
5.5 Sensitive Receptors 5-12

6 METHODS FOR EVALUATING EFFECTS 6-1
6.1 Definition of Resource Study Area 6-1
6.1.1 Statewide 6-1
6.1.2 Regional 6-1
6.1.3 Local 6-1
6.2 Statewide and Regional Operations Emissions Calculations 6-2
6.2.1 On-Road Vehicles 6-2
6.2.2 Trains 6-2
6.2.3 Aircraft 6-3
6.2.4 Power Plants 6-3
6.3 Local Operations Emissions Calculations 6-3
6.3.1 Stations 6-3
6.3.2 Maintenance Facilities 6-5
6.3.3 Sulfur Hexafluoride Circuit Breakers 6-7
6.3.4 Microscale Carbon Monoxide Hot Spot Analysis 6-7
6.3.5 Particulate Matter (PM_{10} and $PM_{2.5}$) Hot-Spot Analysis 6-10
6.3.6 Mobile Source Air Toxics Analysis 6-11
6.3.7 Operations Health Risk Assessment 6-12
6.4 Construction Emissions Calculations 6-16
6.4.1 Construction Activities 6-16
6.4.2 Construction Approach 6-16
6.4.3 Models and Methods for Mass Emissions Modeling 6-17
6.4.4 Ballast and Subballast Hauling 6-18
6.4.5 Daily and Annual Emissions Estimates 6-18
6.4.6 Emissions by Air District and Basin 6-18
6.4.7 Project Design Features 6-21
6.4.8 Regulatory Control Measures 6-21
6.4.9 Construction Health Risk Assessment 6-21
6.4.10 Other Localized Construction Effects 6-26
6.5 Asbestos, Lead-Based Paint, Valley Fever, and Odors 6-28

7 AIR QUALITY EFFECTS ANALYSIS 7-1
7.1 No Project Alternative 7-1
7.2 Statewide and Regional Operational Emissions Analysis 7-2
7.2.1 On-Road Vehicles 7-2

7.2.2 Trains 7-2
7.2.3 Aircraft 7-9
7.2.4 Power Plants 7-9
7.2.5 Regional Operations Criteria Pollutant Emissions Summary 7-13
7.3 Local Operation Emission Sources 7-19
7.3.1 Station Sites and Maintenance Facilities 7-19
7.4 Total Operations Emissions 7-20
7.5 Microscale Carbon Monoxide Hot-Spot Analysis 7-27
7.6 Particulate Matter (PM_{10} and $PM_{2.5}$) Hot-Spot Analysis 7-31
7.7 Mobile Source Air Toxics 7-32
7.7.1 Regional Mobile Source Air Toxics 7-32
7.7.2 Local Mobile Source Air Toxics 7-33
7.7.3 Mobile Source Air Toxics Research and Incomplete Information 7-33
7.8 Operations Health Risk Assessment 7-33
7.8.1 Freight Relocation 7-33
7.8.2 Stations and Maintenance Facilities 7-39
7.9 Construction Mass Emissions Analysis 7-40
7.9.1 Total Emissions 7-40
7.9.2 Alternative 1 Yearly and Daily Emissions 7-43
7.9.3 Alternative 2 Yearly and Daily Emissions 7-49
7.9.4 Alternative 3 Yearly and Daily Emissions 7-55
7.9.5 Alternative 4 Yearly and Daily Emissions 7-61
7.10 Construction Health Risk Assessment 7-67
7.11 Other Localized Construction Effects 7-71
7.12 Asbestos, Lead-Based Paint, Valley Fever, and Odors 7-101
7.12.1 Asbestos 7-101
7.12.2 Lead-Based Paint 7-101
7.12.3 Valley Fever 7-101
7.12.4 Odors 7-101
7.13 Summary of Effects 7-102

8 GLOBAL CLIMATE CHANGE EFFECTS ANALYSIS 8-1
8.1 Statewide and Regional Operations Emissions Analysis 8-1
8.1.1 On-Road Vehicles 8-2
8.1.2 Trains 8-3
8.1.3 Aircraft 8-3
8.1.4 Power Plants 8-4
8.1.5 Regional Operations Greenhouse Gas Emissions Summary 8-5
8.2 Local Operations Emissions Sources 8-6
8.2.1 Station Sites and Maintenance Facilities 8-6
8.2.2 Sulfur Hexafluoride Circuit Breakers 8-7
8.3 Total Operations Emissions 8-8
8.4 Construction Greenhouse Gas Emissions 8-9
8.5 Summary of Effects 8-14

9 MITIGATION MEASURES 9-1

10 CUMULATIVE EFFECTS 10-1
10.1 Near- and Long-Term Operations 10-1
10.2 Construction 10-6
10.2.1 Criteria Pollutants 10-6

10.2.2 TACs 10-6
10.3 Combined Construction and Operations Cumulative Health Risk Assessment 10-10
11 CONFORMITY ANALYSIS 11-1
11.1 General Conformity 11-1
11.2 Transportation Conformity 11-2
12 REFERENCES 12-1

EXECUTIVE SUMMARY

The California High-Speed Rail Authority (Authority) has prepared this *San Jose to Merced Project Section Air Quality and Greenhouse Gases Technical Report* to support the *San Jose to Merced Project Section Environmental Impact Report/Environmental Impact Statement*. This technical report characterizes existing conditions and analyzes air quality and greenhouse gas (GHG) effects of four project alternatives.

Air quality and GHG are important considerations because of their effect on human health and global climate change. This technical report addresses effects resulting from construction and operation of the San Jose to Merced Project Section (Project Section), focusing on the portion of the Project Section between San Jose and Carlucci Road (San Jose to Central Valley Wye Project Extent, or simply project). It describes relevant federal, state, regional, and local regulations and requirements; methods used for the analysis of effects; the affected environment; impact avoidance and minimization features (IAMF) that would avoid or minimize effects; and the potential effects on air quality and GHGs in the project resource study area (RSA) that could result from construction and operation of the project alternatives. Emissions and impacts under all four project alternatives are analyzed at an equal level of detail to support the project-level environmental document prepared pursuant to the California Environmental Quality Act (CEQA) and National Environmental Policy Act (NEPA).

Summary of Effects

Air Quality

Construction of all four project alternatives would result in reactive organic gases (ROG)[1] and nitrogen oxide (NO_X) emissions that would exceed the Bay Area Air Quality Management District's (BAAQMD) CEQA thresholds. Construction emissions of NO_X, carbon monoxide (CO), and particulate matter (PM) less than 10 microns in diameter (PM_{10}) would also exceed the San Joaquin Valley Air Pollution Control District's (SJVAPCD) annual CEQA thresholds. None of the project alternatives would result in construction emissions above the Monterey Bay Air Resources District's (MBARD) PM_{10} CEQA threshold. Construction of all project alternatives would also exceed the general conformity *de minimis* NO_X thresholds in the San Francisco Bay Area Air Basin (SFBAAB) and San Joaquin Valley Air Basin (SJVAB).

The project would be built with feasible on-site control measures to reduce emissions and minimize effects on air quality. Fugitive dust emissions would be reduced through implementation of a dust control plan (AQ-IAMF#1: Fugitive Dust Emissions) and best management practices at new concrete batch plants (AQ-IAMF#6: Reduce the Potential Impact of Concrete Batch Plants). The contractor would utilize low-volatile organic compound (VOC) paints to limit the emissions of VOCs, which contribute to ozone (O_3) formation (AQ-IAMF#2: Selection of Coatings). Exhaust-related pollutants would be reduced through use of renewable diesel, Tier 4 off-road engines, and model year 2010 or newer on-road engines, as required by AQ-IAMF#3: Renewable Diesel, AQ-IAMF#4: Reduce Criteria Exhaust Emissions from Construction Equipment, and AQ-IAMF#5: Reduce Criteria Exhaust Emissions from On-Road Construction Equipment. However, even with application of IAMFs, exceedances of air district and general conformity thresholds would still occur.

The Authority would implement mitigation measures to reduce and offset the remaining construction impact on air quality resources. Specifically, AQ-MM#1: Implement Additional On-Site Emissions Controls to Reduce Fugitive Dust identifies additional best management practices for reducing on-site fugitive dust emissions, consistent with BAAQMD (2017b) guidance. AQ-MM#2 requires that a minimum of 25 percent of all light-duty on-road vehicles use zero emission (ZE) or near-zero emission (NZE) technology. The measure also includes ZE and NZE goals for heavy-duty on-road trucks and off-road equipment. AQ-MM#3: Offset Project Construction

[1] ROG is synonymous with volatile organic compounds (VOC); both terms are used in this document depending on the emissions source.

Emissions in the San Francisco Bay Area Air Basin would offset ROG and NO_X emissions to below BAAQMD thresholds or net zero (as required by the General Conformity regulation). AQ-MM#4: Offset Project Construction Emissions in the San Joaquin Valley Air Basin would fully offset (i.e., to net zero) all emissions of ROG, NOx, and PM within the SJVAPCD, pursuant to the Authority's Memorandum of Understanding (MOU) with the air district for the HSR subsections within the SJVAB. Pursuant to SJVAPCD's Guide for Assessing and Mitigating Air Quality Impacts, emissions offsets procured through AQ-MM#4 could not be used to mitigate CO effects. Accordingly, CO emissions would remain above SJVAPCD's CEQA threshold even after implementation of all feasible mitigation.

Within the BAAQMD, Alternatives 2 and 4 would result in comparable levels of total emissions and Alternatives 1 and 3 would result in comparable levels of total emissions. Alternatives 2 and 4 would result in the greatest emissions primarily because of embankment activities in the Morgan Hill and Gilroy Subsection, in contrast to viaduct construction under Alternatives 1 and 3, which requires less earthmoving and equipment and vehicles. Maximum daily ROG and NO_X emissions in excess of BAAQMD thresholds would be generated between 2023 and 2025, with the greatest emissions occurring in 2025 under all project alternatives. Daily ROG and NO_X emissions would be highest in 2025 due to concurrent construction activities in the Morgan Hill and Gilroy Subsection and ballast hauling. Construction and emissions intensity declines after 2025 once earthmoving and other equipment-intensive activities are complete.

Within the MBARD, total annual construction emissions are highest under Alternatives 2 and 4 because of embankment activities in the Morgan Hill and Gilroy Subsection and more movement of ballast through the North Central Coast Air Basin (NCCAB). Embankment construction generally requires more equipment and vehicles than viaduct construction, resulting in greater emissions. In addition, berm and embankment construction requires more ballast, which results in more ballast hauling and associated emissions. In general, emissions under all alternatives would be highest during the first few years of construction when earthmoving and other emissions-intensive activities would occur. Emissions would peak again in 2027 and 2028 due to ballast hauling through the NCCAB.

Within the SJVAPCD, all project alternatives would result in the same amount of emissions because construction activities would be identical. Similar amounts of annual emissions would be generated during each year of construction between 2022 and 2027. Emissions would decline in 2028 once tunneling and other emissions-intensive activities are completed.

Construction activities would not generate emissions in excess of applicable local air district health risk thresholds. Construction of all alternatives would lead to new violations of the PM_{10} and PM less than 2.5 microns in diameter ($PM_{2.5}$) national ambient air quality standards (NAAQS) and California ambient air quality standards (CAAQS), as well as potentially contribute to existing PM_{10} and $PM_{2.5}$ violations through exceedances of the significant impact levels. Alternatives 1, 2, and 4 would also violate the 1-hour nitrogen dioxide NAAQS and CAAQS. Project features would minimize air quality effects (AQ-IAMF#1 through AQ-IAMF#6), although emissions would still violate the ambient air quality standards. These project design features represent all best available on-site controls to reduce construction emissions, and no mitigation is available.

Long-term operation of the project would result in a decrease in all criteria pollutant emissions when compared to 2015 existing and 2029 and 2040 No Project conditions. These patterns apply to all ridership scenarios and alternatives and would be beneficial to the SFBAAB, NCCAB, and SJVAB in meeting their criteria pollutant attainment goals. Regionally and locally, additional vehicle traffic at new and expanded transit stations and maintenance facilities would not result in CO or PM hot spots. Similarly, displaced vehicle miles traveled would reduce regional mobile source air toxics (MSAT) throughout the RSA. While localized MSATs near stations and maintenance facilities may slightly increase as a result of additional passenger traffic, long-term emissions would be substantially reduced because of implementation of state and national vehicle and fuel regulations.

The project would reposition existing Union Pacific Railroad tracks under all four alternatives. Redistributing or moving existing freight traffic would increase long-term toxic air contaminant

(TAC) concentrations at certain receptor locations and would result in corresponding decreases at other locations. Likewise, additional generators at the stations and maintenance facilities proposed under all four project alternatives, new bus service at the East Gilroy Station under Alternative 3, and maintenance operations at the Gilroy maintenance of way facility (MOWF) under all four project alternatives would increase long-term TAC concentrations. Analysis of TAC concentrations from relocated freight service, additional generators, East Gilroy bus service, and MOWF operations indicates that these sources would not result in long-term cancer or noncancer health risks in excess of established thresholds.

The project alignment within the SFBAAB would be in an area that can contain naturally occurring asbestos (NOA). However, the design-build contractor would prepare a congestion management program (CMP) that outlines practices for avoiding and minimizing NOA. Construction contractors would also be required to comply with the BAAQMD's Asbestos Airborne Toxic Control Measure for Construction and Grading Operations, which requires implementation of dust control measures to limit the potential for airborne asbestos. Asbestos-containing materials and lead-based paint may be found during demolition activities, although all four project alternatives would comply with all *National Emission Standards for Hazardous Air Pollutants* regulations. Similarly, implementation of all feasible dust control measures (AQ-IAMF#1) would minimize receptor exposure to Coccidioides immitis fungus spores, if present in the soil during earthmoving activities. While odors may be generated during construction and operation, they would not be substantial and are not expected to result in nuisance complaints.

Greenhouse Gases

Long-term operation of the project would result in a net reduction of regional and statewide GHG emissions when compared to 2015 Existing and 2029 and 2040 No Project conditions. Construction-related emissions would be less than 0.15 percent of the total annual statewide GHG emissions. Total amortized GHG construction emissions for the project are estimated to be between 14,870 and 20,043 metric tons carbon dioxide equivalent per year, with Alternative 4 generating the most emissions, and Alternative 1 generating the least. The increase in GHG emissions generated during construction would be offset in approximately 8 to 14 months by net GHG reductions during operations because of reduced car and aircraft trips in Northern California and statewide. Accordingly, implementation of the project would result in a net decrease in GHG emissions that would be beneficial to the RSA and State of California and would help meet local and statewide GHG reduction goals.

This Page Intentionally Left Blank

1 INTRODUCTION

Since publication of the Draft Environmental Impact Report (EIR)/Environmental Impact Statement (EIS), the following substantive changes have been made to this appendix:

- Where appropriate, the verb "would," when used specifically to describe impact avoidance and minimization features (IAMF) or mitigation measures, as well as their directly related activities, was changed to "will," indicating their integration into project design.
- Emissions generated by light-duty gasoline-powered vehicles used during construction were remodeled to include the effects of the Safer Affordable Fuel-Efficient (SAFE) Vehicles Rule. The adjustment factors were conservatively applied to the entire CalEEMod output for on-road mobile and entire modeled CO concentration, which includes emissions contributions from gasoline and diesel-powered vehicles. The revised emissions results are presented in Tables 7-14 through 7-18, 7-22 through 7-34, 7-52, and 8-6.
- In Section 6.4.9.3, Risk Calculations, text was revised to state that, for risk factors for health risk assessment (HRA) calculations, all receptors were conservatively modeled with residential exposure parameters.
- Section 7, Air Quality Effects Analysis, and Section 8, Global Climate Change Effects Analysis, were updated to state that the emission savings due to reduced vehicle miles traveled (VMT) and mobile source emissions are conservative because they do not consider the recently enacted SAFE Vehicles rule.
- The percentage of future electricity generated by renewable resources required by state law was updated to 100 percent by 2045.
- The analysis now uses a lower *de minimis* threshold (i.e., 70 tons per year rather than 100 tons per year) for particulate matter smaller than or equal to 2.5 microns in diameter ($PM_{2.5}$) and sulfur dioxide (SO_2) in the San Joaquin Valley Air Basin (SJVAB), as shown in Tables 7-25, 7-28, 7-31, and 7-34.
- Refinements were made to the particulate matter mass emissions inventory to more comprehensively capture emissions reductions that would be achieved through implementation of AQ-IAMF#1: Fugitive Dust Emissions. These revisions were made for the final air quality analysis, as reported in Tables 7-22 through 7-34.
- Draft EIR/EIS Mitigation Measure AQ-MM#2 was deleted due to the impact of the SAFE Vehicles Rule. With this Rule, none of the project alternatives would exceed Monterey Bay Air Resources District's (MBARD) coarse particulate matter (PM_{10}) threshold. Text was modified throughout to reflect this change, including in Table 7-52.
- A new air quality mitigation measure, AQ-MM#1: Implement Additional On-Site Emissions Controls to Reduce Fugitive Dust, was added in response to public comments.
- A new air quality mitigation measure, AQ-MM#2: Construction Emissions Reductions – Requirements for use of Zero Emission (ZE) and/or Near Zero Emission (NZE) Vehicles and off-road equipment, was added to reflect the California High-Speed Rail Authority's (Authority) commitment to electric vehicles.
- Statewide operational greenhouse gas (GHG) emissions from electrical generation were revised based on the U.S. Environmental Protection Agency's (USEPA) latest publication of the Emissions and Generation Resource Integrated Database (released January 2020). This resulted in changes to Tables 7-18, 8-1, 8-4, 8-5, and 8-7 through 8-12.
- Text was added to state that, in April 2021, the National Highway Transportation Safety Administration (NHTSA) issued a notice of proposed rulemaking to repeal the SAFE Vehicles Rule. The fate of the SAFE Vehicles Rule remains uncertain in the face of pending litigation by California and others.

- The list of district rules the project may be subject to was updated in Section 3.3.1.1, Bay Area Air Quality Management District, to include Regulation 6, Rule 6 (Prohibition of Trackout).
- Tables 6-3, 7-19, and 10-1 were updated to include the track shift near West Julian Street and North Montgomery Street that would only occur under Alternative 4 with the Diridon design variant.
- Section 6.4.7, Project Design Features, was updated to reflect emissions benefits achieved by AQ-IAMF#1.

This report presents the air quality and GHG technical evaluation for the California High-Speed Rail (HSR) San Jose to Merced Project Section (Project Section), focusing on the portion of the Project Section between San Jose and Carlucci Road (San Jose to Central Valley Wye Project Extent, or project), prepared in support of environmental reviews required under the National Environmental Policy Act (NEPA) and California Environmental Quality Act (CEQA).

1.1 Background of the HSR Program

The Authority proposes to construct, operate, and maintain an electric-powered HSR system in California, connecting the San Francisco Bay Area (Bay Area) and Central Valley to Southern California. When completed, the nearly 800-mile train system would provide new passenger rail service to more than 90 percent of the state's population. More than 200 weekday trains would serve the statewide intercity travel market. The system would be capable of operating speeds up to 220 miles per hour (mph) in certain HSR sections, with state-of-the-art safety, signaling, and automatic train control (ATC) systems. The California HSR System would connect and serve the state's major metropolitan areas, extending from San Francisco to Los Angeles and Anaheim in Phase 1, with extensions to Sacramento and San Diego in Phase 2.

The Authority and Federal Railroad Administration (FRA) commenced their tiered environmental planning process with the 2005 *Final Program Environmental Impact Report (EIR)/Environmental Impact Statement (EIS) for the Proposed California High-Speed Train System* (Statewide Program EIR/EIS) (Authority and FRA 2005). After completion of the first-tier programmatic environmental documents,[2] the Authority and FRA began preparing second-tier project environmental evaluations for sections of the statewide HSR system. Chapter 2, Description of the San Jose to Central Valley Wye Project Extent, of this analysis provides details of the project and the four alternatives under consideration.

1.2 Purpose of this Technical Report

This report supports the San Jose to Merced Project Section EIR/EIS. The resource assessment presented in this analysis is consistent with the Authority and FRA's *California High Speed Rail Project EIR/EIS Environmental Methodology Guidelines Version 5.09,* adopted in April 2017 (Authority and FRA 2017), as well as the following technical guidance manuals:

- Bay Area Air Quality Management District's (BAAQMD) *California Environmental Quality Act Air Quality Guidelines* (BAAQMD 2017a)
- Federal Highway Administration's (FHWA) Memorandum*: Updated Interim Guidance on Mobile Source Air Toxic Analysis in NEPA Documents* (FHWA 2016)
- Office of Environmental Health Hazard Assessment's (OEHHA) *The Air Toxics Hot Spots Program Guidance Manual for Preparation of Health Risk Assessments* (OEHHA 2015)
- MBARD's *CEQA Air Quality Guidelines* (MBUAPCD 2008)

[2] Two program-level environmental documents were prepared: the Final Program EIR/EIS for the Proposed California High-Speed Train System (Authority and FRA 2005) and the Bay Area to Central Valley High-Speed Train Final Program EIR/EIS (Authority and FRA 2008). These documents evaluated the impacts of proposed HSR corridors and selected the HSR sections constituting the California HSR System.

- San Joaquin Valley Air Pollution Control District's (SJVAPCD) *Guidance for Assessing and Mitigating Air Quality Impacts* (SJVAPCD 2015a)

1.3 Organization of this Technical Report

This technical report includes the following chapters in addition to this introductory chapter:

- Chapter 2, Description of the San Jose to Central Valley Wye Project, describes the alternatives as currently proposed.
- Chapter 3, Laws, Regulations, and Orders, introduces federal, state, and local laws, regulations, and policies relevant to air quality and GHGs.
- Chapter 4, Pollutants of Concern, describes the key criteria pollutants, toxic air contaminants (TAC), and GHGs of concern for the project.
- Chapter 5, Affected Environment, discusses existing conditions, including air quality and global climate change in the resource study area (RSA).
- Chapter 6, Methods for Evaluating Effects, describes the analytical methods and assumptions used to determine the effects of the project on air quality and GHG.
- Chapter 7, Air Quality Effects Analysis, assesses potential effects of construction and operations of the project alternatives on ambient air quality and human health.
- Chapter 8, Global Climate Change Effects Analysis, assesses the potential effects of construction and operations of the project alternatives on GHGs and climate change.
- Chapter 9, Mitigation Measures, presents mitigation measures to reduce air quality effects.
- Chapter 10, Cumulative Effects, assesses the potential for construction and operations of the project alternatives, in combination with past, present, and reasonably foreseeable projects, to result in cumulative air quality or GHG effects.
- Chapter 11, Conformity Analysis, presents the general conformity determination for the applicant-preferred alternative consistent with Clean Air Act (CAA) 40 Code of Federal Regulations (C.F.R.) Section 93.158(c).
- Chapter 12, References, provides complete reference information for the published, online, agency, institutional, and individual sources consulted in preparation of this report.
- Chapter 13, Preparer Qualifications, presents the credentials of the staff who oversaw the preparation of this report.
- Supporting information is provided in the following appendices:
  - Appendix A, CalEEMod Outputs for Station and Maintenance Facility Operation, MOWF Calculations, and East Gilroy Transit Calculations, provides the California Emissions Estimator Model (CalEEMod) output files for the local analysis of criteria pollutants and GHG emissions from operation of the stations and maintenance facilities. Assumptions and spreadsheets for the maintenance of way facility (MOWF) and East Gilroy transit calculations are also provided.
  - Appendix B, CALINE4 Outputs for CO Hot-Spot Analysis, provides the CALINE4 output files for the localized carbon monoxide (CO) hot-spot analysis.
  - Appendix C, Construction Emission and Cumulative HRA Assumptions, provides the construction inventory and emission factor assumptions for the analysis of criteria pollutants and GHG emissions from construction of the project, as well as the ambient sources assumed in the cumulative HRA.
  - Appendix D, Ballast Hauling Memorandum, describes quarry selection process and scenario analysis performed for the ballast-hauling assessment.
  - Appendix E, Localized Impacts from Construction, describes air dispersion modeling methods for evaluating localized air quality effects.

- Appendix F, Potential Impact from Induced Winds, provides calculations and analysis details for the induced wind analysis.
- Appendix G, Council on Environmental Quality Provisions Covering Incomplete or Unavailable Information, describes incomplete or unavailable information for mobile source air toxics (MSAT).

2 DESCRIPTION OF THE SAN JOSE TO CENTRAL VALLEY WYE PROJECT

The Project Section would provide HSR service between Diridon Station in downtown San Jose and a station in downtown Merced, with a Gilroy station either in downtown Gilroy or east of Gilroy. The Project Section is designed to allow trains to and from the Bay Area to transition smoothly from north-south to east-west travel with a minimum reduction in speed to achieve the Proposition 1A operational service time requirement. Proposition 1A requires that the system be designed to be capable of a nonstop operational service time of 2 hours and 10 minutes between San Jose and Los Angeles Union Station.[3] The Project Section follows existing transportation corridors to the extent feasible, as directed by Proposition 1A.[4]

The Project Section is comprised of three project extents (Figure 2-1):

- From Scott Boulevard in Santa Clara to Carlucci Road in Merced County, at the western terminus of the Central Valley Wye (the project)
- The Central Valley Wye, which connects the east-west portion of HSR from the Bay Area to the Central Valley with the north-south portion from Merced to Fresno
- The northernmost portion of the Merced to Fresno Project Section, from the northern limit of the Central Valley Wye (Ranch Road) to the Merced Station

The project would connect San Jose to the Central Valley portion of the HSR system at the Central Valley Wye in Merced County, which in turn connects to the portion of the system running north to Merced and south to Fresno and Southern California. Because the portion of the Project Section between Carlucci Road and Merced has been analyzed in the *Merced to Fresno Section Final EIR/EIS* (Authority and FRA 2012a) and the *Merced to Fresno Section: Central Valley Wye Supplemental EIR/EIS* (Authority 2019a), the analysis in this document focuses on the project extent between Scott Boulevard and Carlucci Road (the project).

[3] Proposition 1A requires that the HSR system be designed to achieve a nonstop operational service time of 2 hours and 40 minutes between San Francisco and Los Angeles Union Station, including a 30-minute ride between San Francisco and San Jose (Streets & Highways Code § 2704.09(b)(4)).

[4] Proposition 1A directs that the HSR system maximize use of existing transportation and utility corridors to the extent feasible (Streets & Highways Code § 2704.09(g)).

Figure 2-1 Proposed San Jose to Merced Project Section

2.1 Summary of Design Features

While the northern service limit of the project would be the San Jose Diridon Station, the engineering design and evaluation includes infrastructure and train operations north to Scott Boulevard to serve the San Jose Diridon Station; this additional analysis overlaps with the analysis of the San Francisco to San Jose Project Section to the north. The project is an approximately 90-mile portion of the 145-mile-long Project Section, which includes dedicated or blended[5] HSR track and systems; HSR stations located at San Jose Diridon and Gilroy; a maintenance of way facility (MOWF) in the Gilroy area; and a maintenance of way siding (MOWS) near Turner Island Road in the Central Valley (Figure 2-2). HSR stations at San Jose Diridon and Gilroy would support transit-oriented development, provide an interface with regional and local mass transit services, and provide connectivity to the South Bay and Central Valley highway network.[6] While the northern service limit of the project would be the San Jose Diridon Station, the engineering design and evaluation includes train operations north to Scott Boulevard in Santa Clara to support the independent utility of an HSR station at Diridon Station and to describe the proposed interface of HSR alternatives with blended Caltrain railroad infrastructure. This additional analysis between San Jose Diridon Station and Scott Boulevard overlaps with the analysis of the San Francisco to San Jose Project Section to the north. Under three alternatives, the transition of HSR infrastructure and operations from the blended system between San Francisco and Santa Clara to a fully dedicated system south of the San Jose Diridon Station would occur at either Scott Boulevard or near Interstate (I-) 880. A fourth alternative would extend the blended system through San Jose to Gilroy. The project would extend south from San Jose to Gilroy, then east through the Pacheco Pass to the Central Valley to end at Carlucci Road, the western boundary of the Central Valley Wye.

5 *Blended* refers to operating HSR trains with existing intercity, commuter, and regional trains on shared infrastructure.

6 *South Bay* refers to Santa Clara County.

JUNE 2019

Figure 2-2 Overview of Subsection Design Options

The project comprises the following five subsections:

- **San Jose Diridon Station Approach**—Extends approximately 6 miles from north of San Jose Diridon Station at Scott Boulevard in Santa Clara to West Alma Avenue in San Jose. This subsection includes San Jose Diridon Station and overlaps the southern portion of the San Francisco to San Jose Project Section.
- **Monterey Corridor**—Extends approximately 9 miles from West Alma Avenue to Bernal Way in the community of South San Jose. This subsection is entirely within the city of San Jose.
- **Morgan Hill and Gilroy**—Extends approximately 30–32 miles from Bernal Way in the community of South San Jose to Casa de Fruta Parkway/State Route (SR) 152 in the community of Casa de Fruta in Santa Clara County.
- **Pacheco Pass**—Extends approximately 25 miles from Casa de Fruta Parkway/SR 152 to I-5 in Merced County.
- **San Joaquin Valley**—Extends approximately 18 miles from I-5 to Carlucci Road in unincorporated Merced County.

The Authority and FRA have developed four end-to-end alternatives for the project (Figure 2-2). Table 2-1 shows the design options that distinguish the alternatives by subsection; Figures 2-3 through 2-7 illustrate the features of the four alternatives by subsection.

Figure 2-7 San Joaquin Valley Subsection

2.2 Description of Alternatives

This section describes the proposed design options of the project alternatives in each subsection. The alternatives are similar in length, differing only in the Morgan Hill and Gilroy Subsection, where divergent alignments in Morgan Hill and the alternative alignments through the Downtown Gilroy Station and the East Gilroy Station result in linear variations.

2.2.1 Alternative 1

Development of Alternative 1 was intended to minimize the project footprint, minimize ground disturbance, minimize continuous surface features, and decrease necessary right-of-way acquisition through extensive use of viaduct structures and bypassing downtown Morgan Hill. The HSR alignment for this alternative would consist of 45.4 miles of viaduct, 4.3 miles at grade, 21.9 miles of embankment, two tunnels totaling 15.0 miles, and 2.3 miles in trench.

2.2.1.1 San Jose Diridon Station Approach Subsection

Alignment and Ancillary Features

The San Jose Diridon Station Approach Subsection, from Scott Boulevard in Santa Clara to West Alma Avenue in San Jose, would be approximately 6 miles through the cities of Santa Clara and San Jose (Figure 2-3). The existing Caltrain track in this subsection consists of a predominantly two-track and three-track at-grade alignment. South of De La Cruz Boulevard, the Union Pacific Railroad (UPRR) tracks of the Coast Line from the northeast converge with the Caltrain corridor tracks and continue south adjacent to the east side of the railroad corridor to the Santa Clara Caltrain Station. Between the Caltrain College Park Station and San Jose Diridon Station, Caltrain's Central Equipment Maintenance and Operations Facility comprises three mainline tracks, a maintenance building, and nine yard tracks. San Jose Diridon Station includes five passenger platforms served by nine yard tracks along the west side of the station house. HSR diverges from the Caltrain corridor at Park Avenue, just south of San Jose Diridon Station, and returns to the Caltrain corridor at the north end of the Caltrain Tamien Station, which includes a passenger platform served by two tracks and a single through-track.

Alternative 1 would begin at Scott Boulevard in blended service with Caltrain at grade. The blended service would entail several minor realignments of existing Caltrain track between Scott Boulevard and I-880. New UPRR and Caltrain track would be constructed just north of the HSR guideway beginning north of I-880 to just past the Santa Clara Station.

Beginning at I-880 on the southbound approach to West Hedding Street, Caltrain tracks would be realigned to accommodate the HSR tracks. Dedicated HSR tracks would diverge from the Caltrain Mainline Track (MT) 2 and MT3 tracks and continue southeast along the north side of the existing Caltrain corridor, crossing under West Hedding Street. To accommodate the new track configuration, the West Hedding Street roadway overpass would be replaced with a new overpass bridge that would also pass over Stockton Avenue.

Southeast of West Hedding Street, the dedicated HSR tracks would transition from a two-track at-grade configuration to retained fill and finally to a two-track aerial profile. The HSR alignment would begin the short viaduct option by rising on embankment to an approximately 70-foot-high aerial structure. A new bridge structure would be built to carry the realigned UPRR/Caltrain MT2 tracks over the West Taylor Street underpass. University Avenue would become a cul-de-sac. A new pedestrian underpass would be constructed near the alignment of Emory Street to allow Caltrain riders to reach both platforms of the Caltrain College Park Station. The HSR viaduct would also cross over West Taylor Street, then shift horizontally a maximum of 500 feet east of the existing UPRR/Caltrain mainline tracks to maintain high-speed track curvature.

Both legs of the UPRR Warm Springs Subdivision Lenzen Wye would be relocated, and North Montgomery Street would be extended north of the alignment of Lenzen Avenue almost to the former Lenzen Wye to maintain property access beneath the 60-foot-high HSR viaduct. The HSR viaduct would cross over Cinnabar Street, both legs of the relocated Lenzen Wye and North Montgomery Street, West Julian Street, and West Santa Clara Street while curving west toward

the UPRR/Caltrain mainline tracks to enter a new aerial dedicated HSR station at San Jose Diridon Station.

Continuing on an aerial structure, the alignment would diverge from the Caltrain right-of-way south of the San Jose Diridon Station HSR platforms by turning sharply east at the Park Avenue undercrossing of UPRR/Caltrain tracks. The HSR aerial structure would cross over Los Gatos Creek and San Carlos Street, then over Royal Avenue and the intersection of Bird Avenue and Auzerais Avenue, then over the I-280/SR 87 interchange. Continuing south along the east side of SR 87, the HSR aerial structure would cross over West Virginia Street and the Guadalupe River Trail, then over the Caltrain rail bridge, the Guadalupe River, and Willow Street. The HSR aerial structure would continue south over the Caltrain Tamien Station on an alignment between Tamien Station and the SR 87 freeway, transitioning to the Monterey Corridor Subsection at West Alma Avenue.

Wildlife Crossings

There would be no wildlife crossings in this subsection.

Stations

The HSR San Jose Diridon Station would entail a four-track aerial alignment over the existing Diridon Station at approximately 62 feet to top of rail with 1,410-foot-long platforms above the existing Caltrain rail yard centered between Santa Clara Street and Park Avenue. The existing historic train station would remain in place. As illustrated on Figures 2-8 and 2-9, the primary HSR station building would be constructed north of the existing station building but would continue to the south, wrapping around the existing Caltrain station building. The HSR station building would be accessed from the east at three entrances—the main entrance on the east side of the tracks north of the existing Historic Depot next to the future Bay Area Rapid Transit (BART) alignment; an entrance south of the existing historic Diridon Station building; and an entrance on the east side south of the Pacific Gas and Electric Company (PG&E) power station. There would also be three entrances to the HSR station on the west side of the tracks—a north entrance at the end of White Street and two entrances on Laurel Grove Lane, one north and one south. The aerial station would require viaduct columns within the PG&E substation. The HSR station building would encompass 99,289 square feet with a 4,400-square-foot substation and systems building. The concourse would consist of a mezzanine level above the existing Caltrain tracks and below the HSR platforms, with three east-west connections across the tracks at the north, south, and middle.

Existing parking spaces (226) at Cahill Street would be displaced and replaced 1:1 with new parking areas at Cahill and Park Streets and at Stockton and Alameda Streets. HSR parking demand of 1,050 spaces in 2040 would be met by commercially available parking downtown or at the airport. The Authority has provided a Station Area Planning grant to the City of San Jose to advance the implementation of the Diridon Station Area Plan adopted by the San Jose City Council. Through this effort, the City would address short-term parking needs during HSR and BART Phase II construction and would also address plans for transitioning the parking needed during construction to the highest and best use after construction. Another Station Area Planning grant to the (Santa Clara) Valley Transportation Authority (VTA) would fund a San Jose Diridon Station Facilities Master Plan. This grant would develop a parking program to manage parking demand and supply over time to reflect changes in ridership and park-and-ride mode share. These two studies would provide input into a multimodal access plan for the station that would be developed prior to final station design and construction.

Existing underutilized parking capacity at and around the station would be used to meet the estimated HSR parking demand until a station area parking policy and program are implemented. The Authority would rely on commercially available parking to meet HSR parking demand, provided and priced in accordance with local conditions. HSR riders would be able to walk or take a shuttle, such as the City of San Jose's DASH, from parking located downtown or adjacent to the station.

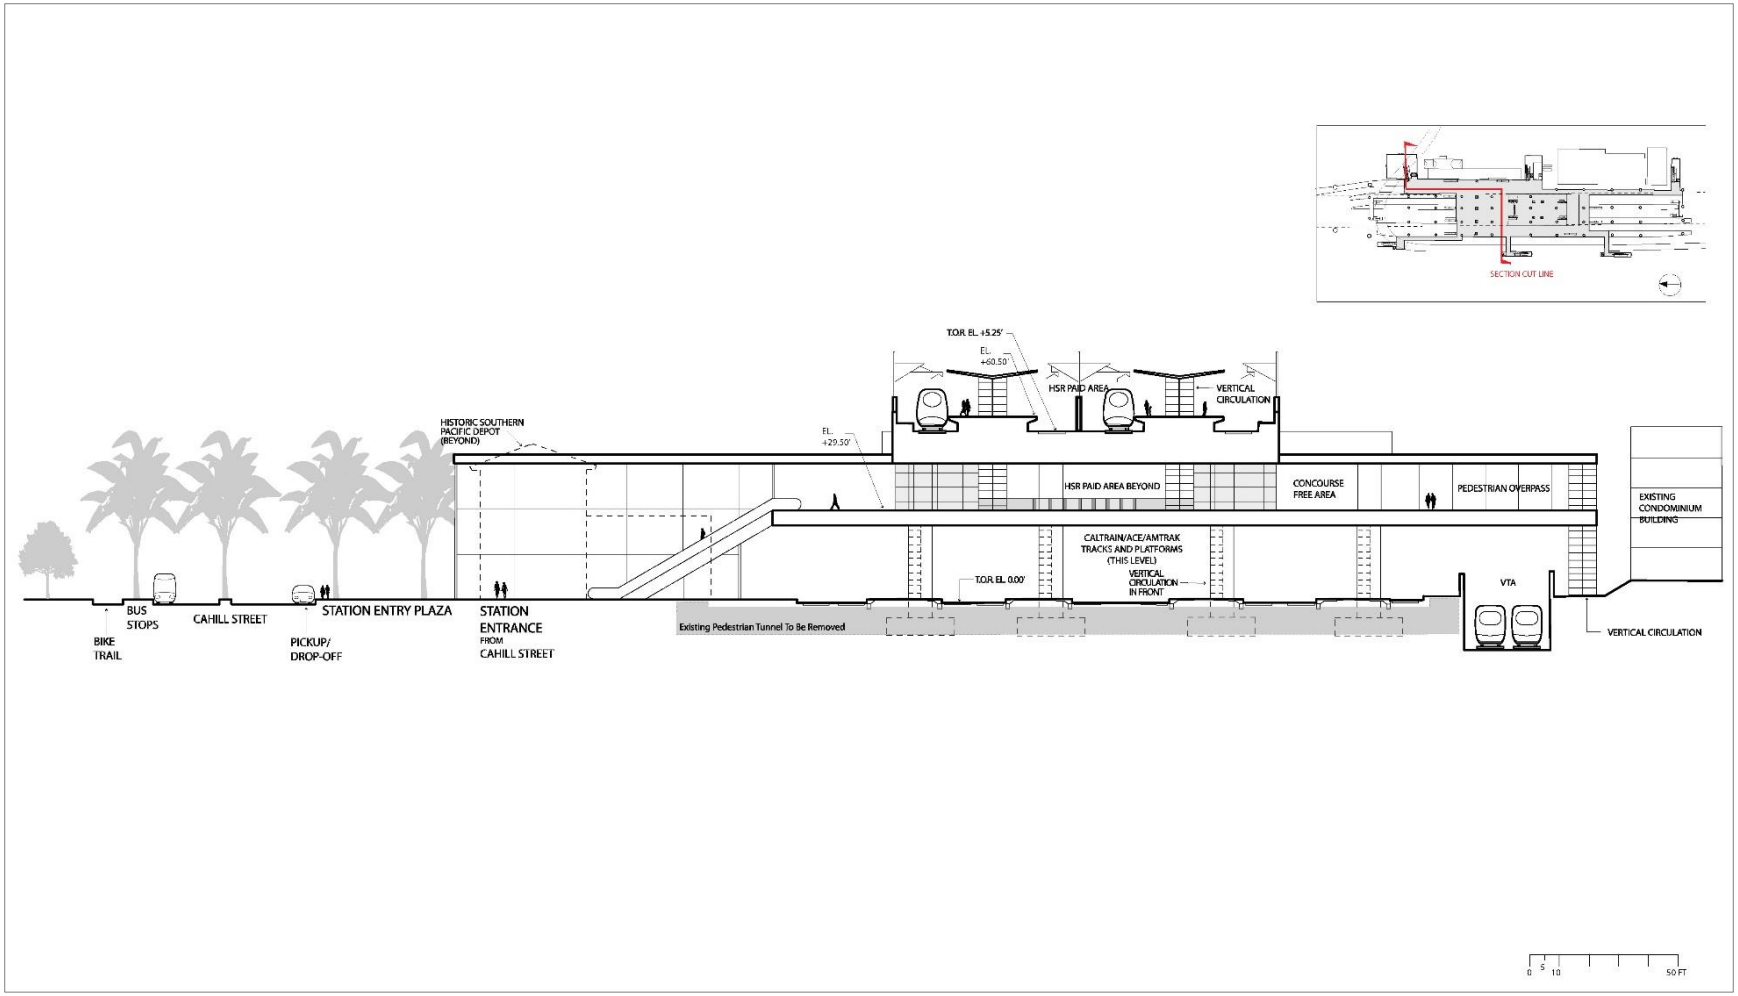
JUNE 2019

Figure 2-8 Conceptual Diridon Aerial Station Plan



Source: Authority 2019b

JUNE 2019

Figure 2-9 Conceptual San Jose Diridon Station Cross Section

The existing off-site bus transit center would be relocated to an on-street facility on Cahill, Stover, and Crandall Streets. Street improvements would include reconfiguring and extending Cahill Street from Santa Clara Street to Park Avenue, and converting Cahill, Stover, and Crandall Streets to a transit street with 12–15 bus stops. Montgomery Street would be reconfigured to provide curb space for a bus layover. A pick-up/drop-off zone of 1,900 square feet would be provided. New two-way cycle tracks would be installed on the east side of Cahill Street. A 4,000-square-foot bicycle facility would be constructed. New signals and pedestrian crossings would be developed at Cahill and Park, Otterson, Stover, West San Fernando, and Crandall Streets.

Other rail operators in the station area are Caltrain, Altamont Corridor Express, Amtrak, VTA light rail, and future BART. VTA has plans to construct new light rail station platforms as a separate project, and BART plans to extend service from the Berryessa Station to Santa Clara with a stop at Diridon by 2026. As a separate project, VTA has plans to construct new light rail station platforms.

Traction Power Sites and Power Connections

One new traction power substation (TPSS) would be constructed in this subsection on the east side of the Caltrain corridor south of I-880 in San Jose (just southeast of the I-880 overcrossing). The TPSS would be interconnected to two new gas-insulated substation breaker-and-a-half bays. The bays would be installed within the fenceline of the PG&E FMC substation, just north of the I-880 overcrossing, via an aerial double-circuit 115-kilovolt (kV) tie-line.

Train Control and Communication Facilities

An enhanced ATC system would control the trains and comply with the FRA-mandated positive train control requirements, including safe separation of trains, over-speed prevention, and work zone protection. This system would include communications towers at intervals of approximately 1.5–3 miles. Signaling and train control elements within the right-of-way would include 10- by 8-foot communications shelters that house signal relay components and microprocessor components, cabling to the field hardware and track, signals, and switch machines on the track. Communications towers in these facilities would use a 6- to 8-foot-diameter 100-foot-tall pole. The communications facilities would be located near track switches and would be grouped with other traction power, maintenance, station, and similar HSR facilities where possible. Where communications towers cannot be co-located with TPSSs or other HSR facilities, the communications facilities would be sited near the HSR corridor in a fenced area approximately 20 by 15 feet.

Under Alternative 1, there would be six ATC sites located between I-880 in San Jose and the I-280 and SR 87 interchange:

- Two sites near the TPSS facility
- One site just north of the San Jose Diridon Station
- Three sites between Park Avenue and the proposed HSR crossing of SR 87

One stand-alone communications radio site would be constructed, at one of two alternative locations, both south of Scott Boulevard along the east side of the Caltrain corridor.

Maintenance Facility

No maintenance facilities are proposed for this subsection.

2.2.1.2 Monterey Corridor Subsection

Alignment and Ancillary Features

The Monterey Corridor Subsection would be approximately 9 miles long and entirely within the San Jose city limits. From the San Jose Diridon Station Approach Subsection at West Alma Avenue, just south of the Caltrain Tamien Station, the alignment would extend primarily southeast to Bernal Way (Figure 2-4). Alternative 1 would be on viaduct in the median of Monterey Road. UPRR MT1, Caltrain MT2, and Caltrain storage tracks would be shifted east between West Alma Avenue and Caltrain/UPRR control point (CP) Lick, at the southeast base of Communications Hill.

Railroad bridges over Almaden Road and Almaden Expressway would be extended to accommodate the track shift. The UPRR Luther spur track south of Almaden Expressway would also be relocated to accommodate the MT shifts.

From West Alma Avenue, the HSR alignment would descend from a viaduct 54 feet above grade to embankment (i.e., 5 feet or higher) north of Almaden Road. The alignment would continue primarily on embankment to cross over Almaden Road on a short aerial structure, then under Almaden Expressway, then continue south on embankment to at grade under Curtner Avenue. The alignment would continue south primarily at grade along the northern base of Communications Hill and ascend to aerial structure before crossing over and entering the Monterey Road median just south of Hillsdale Avenue. Construction of the viaduct over the existing Caltrain Capitol Station would require falsework over the station if constructed by cast-in-place methods or would require relocating the station 500 feet to the south if constructed by precast segments. The alignment would continue south on viaduct in the median of Monterey Road, crossing over Capitol Expressway, Skyway Drive, Branham Lane, Roeder Road/Chynoweth Avenue, Blossom Hill Highway, SR 85/West Valley Freeway, and Bernal Road.

The design assumes a reduction from six to four travel lanes on Monterey Road, beginning south of Southside Drive and continuing to a short distance south of Blossom Hill Road where the existing roadway is already four travel lanes. Three existing mid-block left-turn lanes would be closed because of substandard stopping sight distance. Additionally, the design assumes a combined left-turn and through lane at Palm Avenue.

Wildlife Crossings

There would be no wildlife crossings in this subsection.

Stations

No new HSR stations are proposed for this subsection.

Traction Power Facilities

Two traction power paralleling stations would be constructed in this subsection:

- North of the alignment near Curtner Avenue or south of the alignment at Communications Hill
- South of SR 85 or between Bernal Road and the Bernal Road ramp onto Monterey Road

Train Control and Communication Facilities

One ATC site would be constructed in the Monterey Corridor Subsection at one of two locations east of the guideway in the vicinity of Chynoweth Avenue.

Three stand-alone communications radio sites are proposed:

- Near Almaden Road on the east side of the Caltrain corridor (two site options)
- Near Capitol Expressway (two site options)

Maintenance Facility

No maintenance facilities are proposed for this subsection.

2.2.1.3 Morgan Hill and Gilroy Subsection

Alignment and Ancillary Features

The Morgan Hill and Gilroy Subsection would be approximately 30 to 32 miles long and located south of the Monterey Corridor Subsection (Figure 2-5). From Bernal Way in South San Jose, the alignment would extend through Morgan Hill and San Martin to the Downtown Gilroy Station, then curve generally east across the Pajaro River floodplain and through a portion of northern San Benito County before entering a tunnel (Tunnel 1) at the base of the Diablo Range. The alignment would exit the tunnel at Casa de Fruta Parkway/SR 152 in unincorporated eastern Santa Clara County, where it would transition to the Pacheco Pass Subsection. Alternative 1 in this subsection

would construct the Viaduct to downtown Gilroy design option and an aerial Downtown Gilroy Station.

Beginning at the southern limit of the Monterey Corridor Subsection, the alignment would be on viaduct in the median of Monterey Road. In this four-lane section of the road, the design assumes a combined left-turn and through lane to Palm Avenue. The alignment would begin curving east on viaduct (approximately 40 feet above grade) near Ogier Avenue in Santa Clara County. The northbound lanes of Monterey Road would be realigned at this transition to cross beneath the HSR viaduct between columns of the aerial structure.

After crossing the Coyote Valley on viaduct, the alignment would cross over Burnett Avenue in Morgan Hill and parallel US 101 on the west side of the freeway. Continuing south, the alignment would bypass downtown Morgan Hill by crossing over Cochrane Road and associated freeway ramps, East Main Avenue, East Dunne Avenue and associated freeway ramps, and Tennant Avenue and associated freeway ramps.

South of Tennant Avenue and the city limits of Morgan Hill, the alignment would turn west, relocating the cul-de-sac at Fisher Avenue to the west of the HSR facility, then crossing over Maple Avenue, West Little Llagas Creek, East Middle Avenue, and Llagas Creek before rejoining Monterey Road and the UPRR corridor in the community of San Martin. The crossing of Llagas Creek would allow for wildlife movement by clear-spanning both banks and riparian habitat. New storm drainage infrastructure would be constructed on the west side of the alignment along Llagas Creek. The alignment would continue on viaduct along the east side of UPRR and cross over East San Martin Avenue.

South of Las Animas Avenue and the west branch of Llagas Creek, the alignment would curve east over Leavesley Road and Casey Lane. Continuing south, the viaduct would cross the Gilroy Prep School/South Valley Middle School sports field, a portion of the Gilroy Prep School campus, and Upper Miller Slough (with armor added to the channel to strengthen the stormwater conveyance) before crossing over IOOF Avenue, Lewis Street, Martin Street, East 6th Street, and a realigned East 7th Street, to arrive at the downtown Gilroy station on low viaduct (approximately 33 feet high).

South of the Downtown Gilroy Station, the alignment would continue on viaduct over East 10th Street l. Banes Lane would be reconstructed to provide a standard cul-de-sac. South of the Princevale Channel crossing, the alignment would ascend, still on viaduct, over Luchessa Avenue, US 101, and one spur UPRR track. After branching from the main UPRR track and crossing under the HSR viaduct, the new UPRR track for freight access to the MOWF would be provided to travel at grade on the east side of the new HSR track toward the South Gilroy MOWF site. Both the UPRR track and HSR tracks would cross the City of Gilroy wastewater disposal ponds. Continuing south, the alignment would ascend onto embankment. New storm drainage infrastructure would be constructed on the west side of the alignment at Carnadero Avenue, which would be closed where it meets the alignment. Bloomfield Avenue would be realigned to cross over the South Gilroy MOWF site. Sheldon Avenue would become a cul-de-sac south of the HSR alignment and would be abandoned north of the alignment. Before crossing the Pajaro River, the alignment would ascend onto viaduct.

The HSR alignment south and east of Gilroy would cross an agricultural area in Santa Clara and San Benito Counties that is part of the upper Pajaro River floodplain, historically referred to as Soap Lake. HSR guideway on viaduct would be built over the major watercourses to provide a floodplain crossing that is neutral to the hydrology and hydraulics of the floodplain and to accommodate wildlife movement. Because of the Calaveras fault crossing at this location, Tequisquita Slough would be partially filled by approximately 800 feet of HSR embankment. The embankment area would include cross-culverts and 1.3 acres of adjacent floodwater detention basins; in addition, an extended viaduct over Pacheco Creek would serve to maintain floodplain capacity and function. HSR would be on embankment between Pacheco Creek and Lovers Lane. The alignment would return to viaduct at Lovers Lane. After Lovers Lane, the alignment would continue in a combination of embankment and viaduct until reaching the portal for Tunnel 1 on the east side of SR 152.

After exiting the 1.4-mile Tunnel 1 on the west side of SR 152, the alignment would cross over SR 152 and the southern portion of the Pacheco Creek Valley on an aerial structure south of Casa de Fruta. The alignment would move onto embankment just beyond Southside Way at the western transition to the Pacheco Pass Subsection.

Wildlife Crossings

Three wildlife crossings would be provided at the base of Tulare Hill north of the Metcalf Substation connecting to Coyote Creek. The existing culvert under Monterey Road at Fisher Creek would be realigned and replaced with a larger box culvert to improve wildlife movement under Monterey Road and the HSR track. The crossing of Llagas Creek would allow for wildlife movement by clear-spanning both banks and riparian habitat. The alignment would be primarily on viaduct through the Soap Lake area to allow for wildlife movement. Viaducts have heights, widths and depths considered to be very favorable for wildlife movement.

Stations

Alternative 1 would enter the Downtown Gilroy Station on aerial structure (Figures 2-10 and 2-11). The HSR Downtown Gilroy Station would be constructed south of the existing Caltrain station. The station approach would be on a low viaduct—approximately 33 feet to top of rail—with dedicated HSR tracks to the east of UPRR between relocated Old Gilroy/7th Streets and 9th Street. The 800-foot platforms would be on the east and west side of the HSR tracks. The new HSR station building would have both east and west entrances: the main entrance for passengers arriving by auto or bicycle would be on the east side while the main entrance for passengers arriving on foot or by transit would be on the west side. The HSR station building would encompass 60,513 square feet with a 4,400-square-foot substation and systems building. The concourse would be below the new HSR tracks.

The existing 471 Caltrain parking spaces on the west side of the station would be replaced 1:1 by either reconfiguring parking on the west side of the station or relocating it to the east side of the station. The existing 269 San Ysidro housing development parking spaces would be replaced 1:1 with new surface parking at the south end of Alexander Street. HSR parking demand would be 970 spaces in 2040. In addition, the station site plan provides 970 new parking spaces in five areas, for a total of 1,710 parking spaces in 2040. One site would be west of the station along Monterey Road at 9th Street. The other four would be east of the station along Alexander Street at Old Gilroy Street, 9th Street, 10th Street, and Banes Lane. A multimodal access plan would be developed prior to design and construction of the station. The plan would be developed in coordination with local agencies and would include a parking strategy that would confirm the location, amount, and phasing of parking.

A total of eight bus bays would be provided. Street improvements would include realignment of Old Gilroy Street at East 7th Street; existing grade crossings would remain unchanged. A 4,000-square-foot bicycle facility would be constructed. Class II bike lanes would be provided on 7th and Alexander Streets.

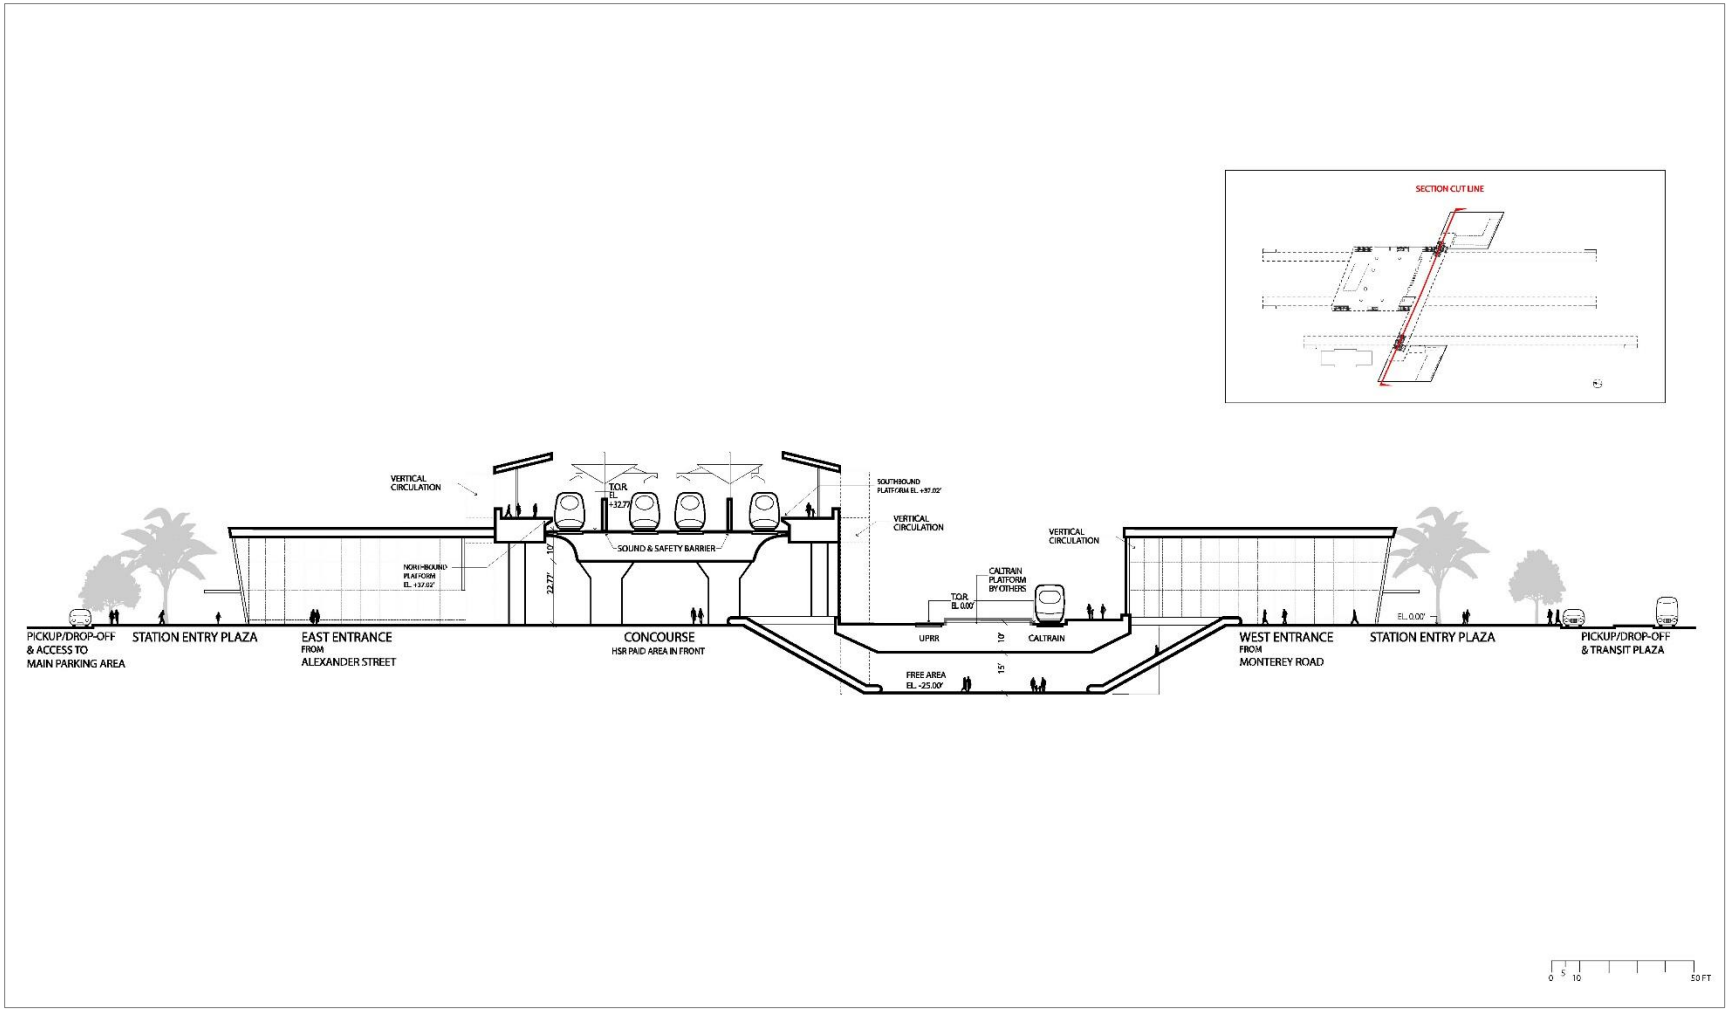
JUNE 2019

Figure 2-10 Conceptual Downtown Gilroy Aerial Station Plan



Source: Authority 2019b

JUNE 2019

Figure 2-11 Cross Section of Downtown Gilroy Station (Viaduct)

Traction Power Facilities

One new TPSS, Site 4—Gilroy, would be constructed at one of two alternate locations on the north side of the alignment: either east or west of Bloomfield Avenue. At this site, one new PG&E switching station would be co-located with the TPSS. Communication facilities (i.e., redundant [two underground or one underground and one overhead on existing power structures] fiber optic lines) would also be required to support the electrical interconnections connecting the TPSS to a new utility switching station, to existing PG&E facilities, or both, typically within tie-line/utility corridors. North of Site 4—Gilroy, a traction power switching station would be constructed east of the HSR alignment at a location north of Palm Avenue.

Four traction power paralleling stations would be constructed adjacent to the guideway at the following locations:

- South of the alignment, either south of Diana Avenue or at the intersection of San Pedro Avenue and Walnut Grove Drive
- North of the alignment, either south of Masten Avenue or south of Rucker Avenue
- In the vicinity of Lovers Lane, either south of the alignment and west of Lovers Lane or north of the alignment and west of Lovers Lane
- At Tunnel 1 east portal

PG&E would reinforce the electric power distribution network to meet HSR traction and distribution power requirements by replacing (reconductoring) the 9.8-mile Metcalf to Morgan Hill and the 10.8-mile Morgan Hill to Llagas 115-kV power lines. The existing power lines to be reconductored, reusing the poles and towers, begin at the Metcalf Energy Center in San Jose and continue southeast parallel to the alignment on the east side before crossing to the west side near Ogier Avenue. Continuing on the west side to the Morgan Hill Substation on West Main Avenue in Morgan Hill, the lines then cross the east side of Peak Avenue and Dewitt Avenue, spanning West Dunne Avenue, Chargin Drive, Spring Avenue, and several residences. The alignment would continue south across an open-space area, then follow Sunnyside Avenue for approximately 0.5 mile. The alignment would continue south for approximately 4 miles, spanning additional open-space areas of wineries and the Corde Valle Golf Course. The alignment would then turn east along the north side of Day Road before heading south for approximately 2.5 miles and terminating at the Llagas Substation in Gilroy. Reconductoring at Metcalf Energy Center in San Jose would be required as well.

A permanent overhead distribution electrical power line from TPSS Site 4 to the Tunnel 1 portal location would provide power to the tunnel boring machine during construction and the tunnel fire-life-safety system during operation.

There are alternative sites for power drops at both portals for Tunnel 1. At each portal, one site is north of the alignment and one is south.

Train Control and Communication Facilities

A total of 17 ATC sites would be constructed in the Morgan Hill and Gilroy Subsection for this alternative:

- One site east of Monterey Road near Palm Avenue (two site options)
- One site at East Middle Avenue (two site options)
- One site between Las Animas Avenue and Leavesley Road
- One site south of Leavesley Road
- One site south of Lewis Street
- One site north of 6th Street in Gilroy
- Two sites south of 6th Street in Gilroy
- Two sites north of 10th Street in Gilroy
- One site south of Banes Lane
- Five sites north of Carnadero Avenue

- Three sites east of the Pajaro River
- One site near Lake Road (two site options)

Six stand-alone communication radio sites would be constructed within this subsection:

- Forsum Road or Blanchard Road (two site options)
- Near Bailey Avenue (two site options)
- Between Barnhart Avenue and Kirby Avenue (two site options)
- South of Cochrane Road along US 101 (two site options)
- North of Cox Avenue and south of West San Martin Avenue (two site options)
- East of the Pajaro River, south of Gilroy

Maintenance Facilities

The MOWF under Alternative 1 would be located in South Gilroy between Carnadero Road and Bloomfield Road (Figure 2-12) to accommodate machinery and inspection and maintenance staff. The MOWF would cover approximately 75 acres. The freight connection would be provided as described above.

2.2.1.4 Pacheco Pass Subsection

Alignment and Ancillary Features

The Pacheco Pass Subsection would be approximately 25 miles long. The alignment would generally follow the existing SR 152 corridor east from Casa de Fruta for approximately 17 miles, then diverge north around the Cottonwood Creek ravine of the San Luis Reservoir for approximately 8 miles before transitioning to the San Joaquin Valley Subsection near I-5 (Figure 2-6). Tunnel is the only design option in this subsection.

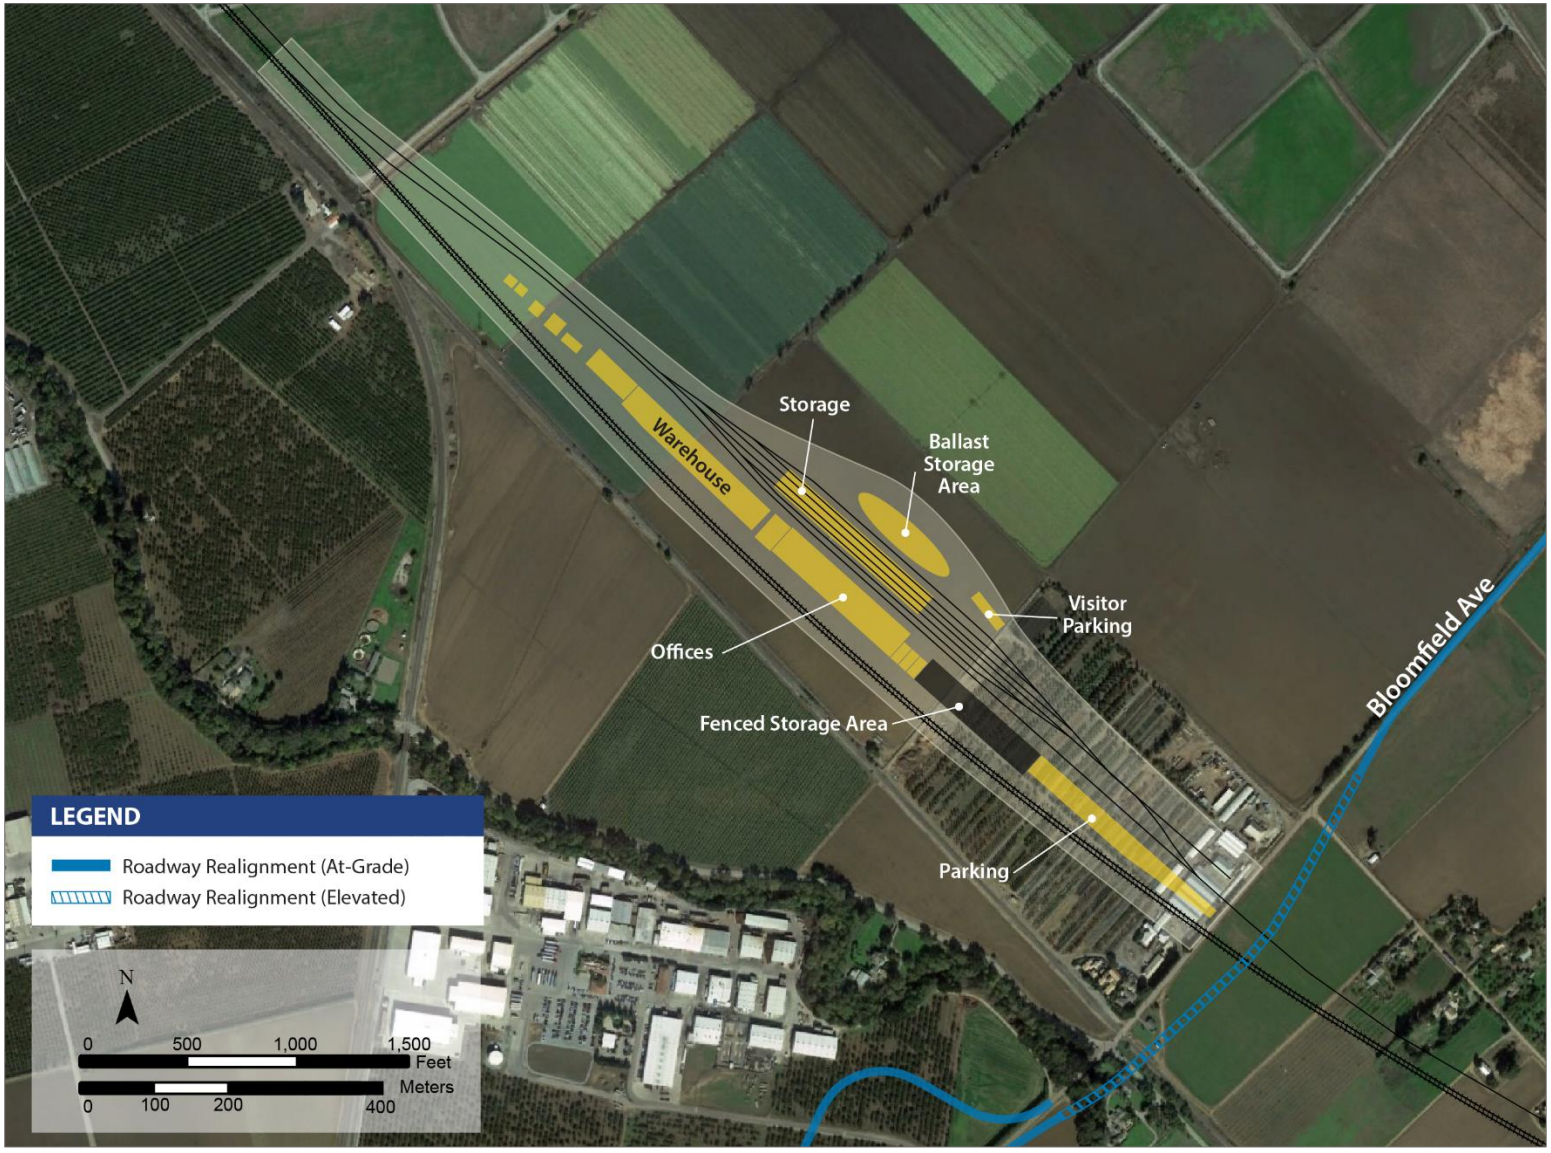
From the eastern limit of the Morgan Hill and Gilroy Subsection, the guideway would transition from aerial structure to embankment along the southern boundary of Casa de Fruta. This stretch of embankment would be on fill or in excavated hillside cuts to accommodate a level HSR guideway profile over varied surface elevations and to control unstable slopes known for vulnerability to landslip (i.e., areas subject to the downward falling or sliding of a mass of soil, detritus, or rock on or from a steep slope). The alignment would ascend to viaduct over Pacheco Creek along the south side of SR 152 and remain on viaduct to the Tunnel 2 portal. This portal would include a staging area for tunnel construction and a permanent area for traction and facility power with access provided by a service road from SR 152. Tunnel 2 would extend northeast approximately 13.5 miles. Access to the Tunnel 2 east portal for HSR construction, operations, and maintenance would be on McCabe Road north of Romero Ranch. Continuing east, the HSR guideway would be predominantly on a combination of embankment and aerial structures, with viaducts over Romero Creek and the California Aqueduct. Romero Road would be realigned at its intersection with I-5. East of I-5, the alignment would cross over SR 33/Santa Nella Road and the CCID Outside Canal before transitioning to the San Joaquin Valley Subsection at Fahey Road.

Wildlife Crossings

Four wildlife crossing culverts would be provided west of the California Aqueduct, with an additional two wildlife crossings between the California Aqueduct and the Delta-Mendota Canal and one between the Delta-Mendota Canal and I-5. Three wildlife crossings would be provided between I-5 and Santa Nella Road, and three more between Santa Nella Road and Fahey Road. Viaducts would also function as wildlife movement areas in this subsection.

Stations

No new HSR stations are proposed for this subsection.



Source: Authority 2019b

JUNE 2019

Figure 2-12 South Gilroy Maintenance of Way Facility

Traction Power Facilities

One new TPSS, Site 5—O'Neill, would be constructed approximately 1.2 miles west of the Calfornia Aqueduct. A new 230-kV double-circuit tie-line would be constructed from the expanded Quinto switching station to the TPSS, paralleling an existing PG&E transmission line for approximately 0.6 mile. The tie-line would be installed either underground in a utility easement or overhead, requiring the existing 500-kV transmission line to be raised. No reinforcements to the PG&E power system would be required for this site. Communication facilities (i.e., redundant [two underground or one underground and one overhead on existing power structures] fiber optic lines) would also be required to support the electrical interconnection. The interconnection would link the TPSS to a new PG&E switching station, to existing PG&E facilities, or both—typically within tie-line/utility corridors.

A traction power switching station would be constructed at each Tunnel 2 portal. A power drop site would be co-located with the switching stations. A new permanent distribution power line from the Quinto switching station along McCabe Road to the Tunnel 2 east portal location would provide power for tunnel construction and fire and life safety systems during operations. The existing PG&E 230-kV Quinto switching station would be expanded within the fence line to support the HSR system.

Traction power paralleling stations would be constructed at three locations:

- Two stations within Tunnel 2 cross passages, approximately 5 miles apart
- One station located either southeast or northwest of the alignment crossing of Fahey Road

Train Control and Communication Facilities

Three ATC sites would be constructed in the Pacheco Pass Subsection at the following locations:

- West portal of Tunnel 2
- Underground within the limits of Tunnel 2
- Adjacent to TPSS Site 5

One stand-alone communications radio antenna site would be constructed in the Pacheco Pass Subsection:

- Near SR 152 and the Tunnel 2 west portal
- 1 mile west of Tunnel 2
- Delta-Mendota Canal crossing

Maintenance Facilities

No maintenance facilities are proposed for this subsection.

2.2.1.5 San Joaquin Valley Subsection

Alignment and Ancillary Features

The San Joaquin Valley Subsection would be approximately 18 miles long, from east of I-5 (at Fahey Road) to the intersection of Henry Miller Road and Carlucci Road in Merced County, where the alignment would connect to the Central Valley Wye (Figure 2-7). The single design option in this subsection is a combination of viaduct and embankment along Henry Miller Road, identified as the Henry Miller Road design option.

South of Fahey Road, the guideway would continue east and cross over three irrigation ditches, Cherokee Road, the CCID Main Canal, two additional irrigation ditches, and adjacent farmland on viaduct. Continuing east, the alignment would be on embankment (including four proposed culvert crossings for irrigation ditches) before ascending on an approximately 1.4-mile-long viaduct over the San Luis (Volta) Wasteway, the UPRR West Side branch line, and Ingomar Grade Road.

The alignment would descend to embankment west of Volta Road while turning southeast before crossing to the south side of Henry Miller Road. Henry Miller Road would be realigned to pass over the HSR alignment on a bridge. The HSR embankment between the Volta Road

overcrossing and Los Banos Creek would cross over two proposed culverts to maintain irrigation canals. The alignment would then ascend to cross over Los Banos Creek and Badger Flat Road on a 0.8-mile-long viaduct before descending onto embankment.

The alignment would continue east for 3.6 miles on embankment, over several combined wildlife crossing/drainage culverts and drainage culverts, including an irrigation ditch at Wilson Road, an irrigation ditch at Johnson Road, two irrigation ditches at Nantes Avenue, the Santa Fe Canal, the San Luis Canal, the San Luis Drain, and the Porter-Blake Bypass. A road would be constructed between Badger Flat Road and Nantes Avenue. SR 165/Mercey Springs Road would be raised to cross over the HSR alignment and Henry Miller Road on a bridge. East of SR 165 and the Santa Fe Grade, the alignment would ascend to an approximately 1.8-mile viaduct south of the Los Banos State Wildlife Area across Mud Slough to maintain wildlife movement within the Grasslands Ecological Area (GEA). Baker Road, Midway Road, and Hereford/Salt Slough would be closed south of Henry Miller Road. Box Car Road would become a cul-de-sac with a new road to the east. Hutchins Road would be abandoned. The alignment would continue on embankment to the eastern limit of the subsection and the project. Culvert crossings would be provided for the San Pedro Canal, Boundary Drain, Lone Tree Canal, Devon Drain, West Delta Drain, West Delta Canal, Dambrosia Ditch, Delta Canal and seepage drain, East Delta Canal, Poso Drain, Belmont Drain, Delta Canal #1, West San Juan Drain, San Juan #1, and several other irrigation ditches and drains in the section of viaduct over the GEA. Several local roadways—Delta Road, Turner Island Road, and Carlucci Road—would be elevated over the HSR guideway, maintaining access to adjacent properties. The alignment would transition to the Central Valley Wye at Carlucci Road.

Wildlife Crossings

The rail alignment would be primarily on viaduct where it overlaps with the GEA boundary and modeled wildlife movement corridors. Three additional wildlife crossing culverts would be added between Fahey Road and Cherokee Road. Regularly spaced wildlife crossing culverts would be provided through the remainder of this subsection. In total, there would be 64 wildlife crossings in this subsection.

Stations

No new HSR stations are proposed for this subsection.

Traction Power Facilities

A traction power switching station would be constructed on the north or south side of the alignment at one of two alternate sites east of the intersection of Henry Miller Road and Santa Fe Grade. Traction power paralleling stations would be constructed at the following locations:

- Either east or west of the Henry Miller Road overcrossing of the HSR alignment near Volta Road (two site options)
- Intersection of Henry Miller Road and Box Car Road (two site options either north or south of the alignment)

Train Control and Communication Facilities

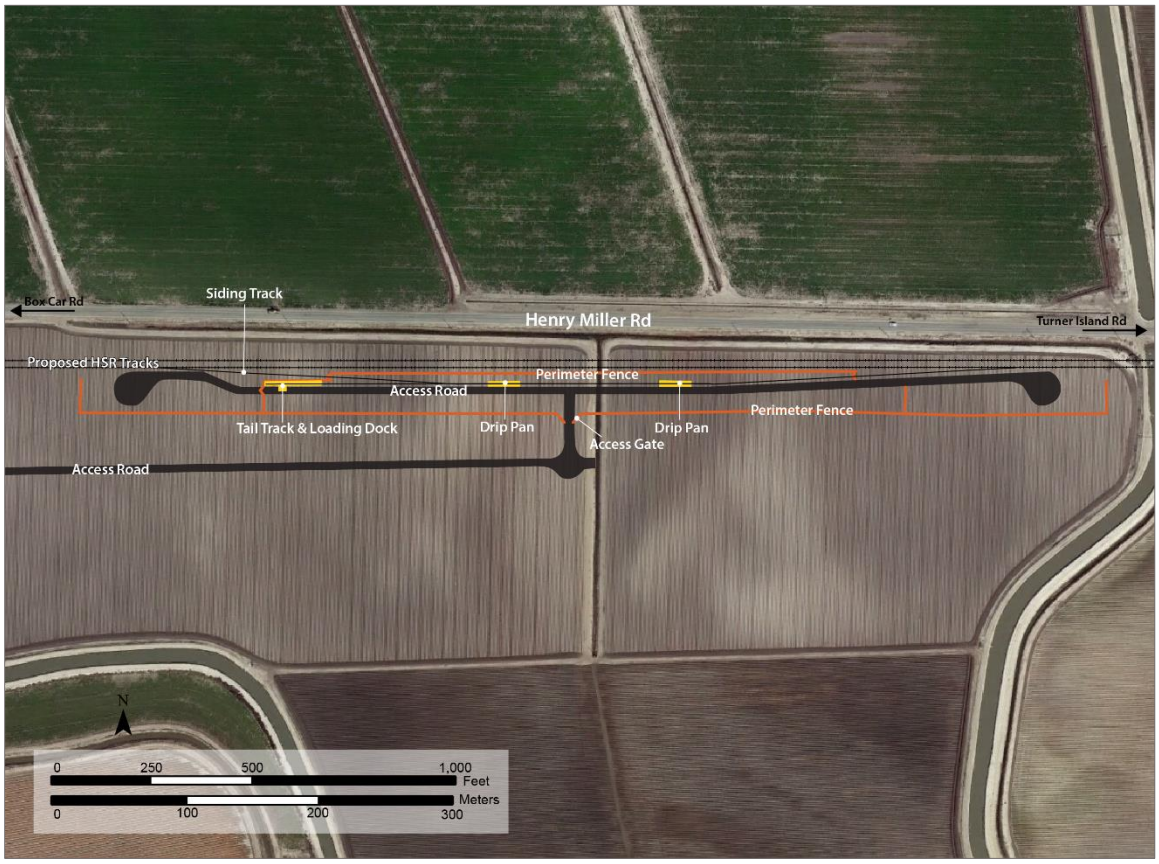
Four ATC sites would be constructed in the San Joaquin Valley Subsection:

- One site east of the CCID Main Canal (two options)
- Three sites near Johnson Road
- One site near Box Car Road (two site options)

One stand-alone communication radio site would be constructed: at Wilson Road (two site options): east of the San Pedro Canal and at Carlucci Road.

Maintenance Facility

An MOWS is proposed near Turner Island Road near the eastern limit of the project (Figure 2-13). The MOWS would be about 0.5 mile long, encompassing about 4 acres. The facility would be constructed near Henry Miller Road to avoid the GEA and other sensitive habitat.



Source: Authority 2019b JUNE 2019

Figure 2-13 Maintenance of Way Siding near Turner Island Road

2.2.2 Alternative 2

Alternative 2 is the alternative that most closely approximates the alignment and structure types identified in the prior program-level documents, implemented by limiting longitudinal encroachment into the UPRR right-of-way to combine railroad grade separations with minimum property displacements. The HSR guideway under this alternative would be comprised of 20.9 miles on viaduct, 8.5 miles at grade, 41.0 miles on embankment, two tunnels totaling 15.0 miles, and 3.2 miles in trench.

2.2.2.1 San Jose Diridon Station Approach Subsection

Alignment and Ancillary Features

Alternative 2 would begin at Scott Boulevard at grade in blended service with Caltrain. Approximately 300 feet south of Scott Boulevard, the HSR tracks would separate from the Caltrain tracks and begin ascending to embankment and then to the 50-foot-tall dedicated viaduct at Main Street. The long viaduct under Alternative 2 would have a wider footprint than the short viaduct to I-880 under Alternative 1, requiring more curve straightening of the Caltrain tracks north of I-880. At the Lafayette Street crossing, the project would replace the existing pedestrian

overpass with an underpass. The existing De La Cruz Boulevard overcrossing would be replaced with an undercrossing to enable the HSR aerial structure to cross 43 feet high over De La Cruz Boulevard, the relocated UPRR MT1 and two industry tracks, and the Caltrain Santa Clara Station. The Santa Clara Station northbound platform would be reconstructed to accommodate the supports for the HSR aerial structure. South of Santa Clara Station, the three relocated UPRR tracks would cross under the HSR viaduct so that all Caltrain and UPRR tracks would be west of the HSR viaduct. The HSR viaduct would then ascend to 68 feet to cross over I-880.

Farther south, the existing West Hedding Street roadway overcrossing would be replaced by an undercrossing under the rail corridor. A short section of retained fill would be used to support the tracks over the future BART to San Jose tunnel. The intersection of Stockton Avenue and University Avenue would be replaced by cul-de-sacs; Emory Street would be a new cul-de-sac on the north side of HSR. The curve from westbound West Taylor Street to northbound Chestnut Street would be realigned for the HSR crossing over West Taylor Street; the alignment would then ascend on a viaduct to cross over Cinnabar Street. The UPRR Warm Springs Subdivision Lenzen Wye would be relocated to the southwest. North Montgomery Street would be extended to Cinnabar Street to maintain property access beneath the 68-foot-high HSR viaduct. The alignment would curve west toward the UPRR/Caltrain MTs before crossing over the western part of the SAP Center parking lot, then over West Santa Clara Street to enter the new dedicated HSR aerial platforms at the San Jose Diridon Station.

Between San Jose Diridon Station and West Alma, Alternative 2 would be identical to Alternative 1. Continuing on an aerial structure, the alignment would diverge from the Caltrain right-of-way south of the San Jose Diridon Station HSR platforms by turning sharply east at the Park Avenue undercrossing of UPRR/Caltrain tracks. The HSR aerial structure would cross over Los Gatos Creek and San Carlos Street, then over Royal Avenue and the intersection of Bird Avenue and Auzerais Avenue, then over the I-280/SR 87 interchange. Continuing south along the east side of SR 87, the HSR aerial structure would cross over West Virginia Street and the Guadalupe River Trail, then over the Caltrain rail bridge, the Guadalupe River, and Willow Street. The HSR aerial structure would continue south over the Caltrain Tamien Station on an alignment between Tamien Station and the SR 87 freeway, transitioning to the Monterey Corridor Subsection at West Alma Avenue.

Wildlife Crossings

There would be no wildlife crossings in this subsection.

Stations

The San Jose Diridon Station would be the same as described for Alternative 1.

Traction Power Facilities

One new TPSS would be constructed on the east side of the Caltrain corridor south of I-880 as described for Alternative 1.

Train Control and Communication Facilities

Alternative 2 would have six ATC sites within this subsection:

- One site at Scott Boulevard
- One site at Main Street
- One site just north of the San Jose Diridon Station
- Three sites between Park Avenue and the proposed HSR crossing of SR 87 (same as under Alternative 1)

No stand-alone communications radio sites would be built in this subsection under Alternative 2.

Maintenance Facilities

No maintenance facilities are proposed for this subsection.

2.2.2.2 Monterey Corridor Subsection

Alignment and Ancillary Features

The Monterey Corridor Subsection is approximately 9 miles long and entirely within the San Jose city limits. However, Alternative 2 would begin the viaduct transition to the Monterey Road/UPRR corridor approximately 400 feet north of the transition under Alternatives 1 and 3 but would be primarily at grade or on embankment upon entering the road/rail corridor. Alterations of existing railroad track and systems between West Alma Avenue and CP Lick (near the east base of Communications Hill) would be the same as under Alternatives 1 and 3, except for a new, continuous intrusion barrier between the existing UPRR tracks and HSR tracks.

From West Alma Avenue, the HSR alignment would descend from a viaduct 54 feet above grade to embankment north of Almaden Road. The alignment would continue primarily on embankment on the west side of the Caltrain/UPRR tracks, crossing over Almaden Road on a short aerial structure, then proceeding at grade under West Almaden Expressway and Curtner Avenue. South of Curtner Avenue, the alignment would continue south at grade along the west side of the Caltrain/UPRR tracks around the northern base of Communications Hill, ascending to aerial structure before crossing over and entering the Monterey Road/UPRR corridor just south of Hillsdale Avenue. On the approach to Monterey Road, the aerial structure would cross over the UPRR tracks and the Caltrain Capitol Station while curving southeast to return to grade within the road/rail corridor northwest of the Capitol Expressway. Monterey Road would be realigned to the east, while HSR would run along the east side of UPRR. South of Fehren Drive, Monterey Road would be reduced from six to four lanes. Continuing south, the alignment would descend into trench beneath a widened Capitol Expressway bridge before ascending to grade at Skyway Drive. Under Skyway Drive Variant A, Monterey Road would retain its current at-grade configuration, and a new connector ramp located northwest of the intersection of Skyway Drive and Monterey Road would connect Monterey Road to the depressed Skyway Drive underpass. San Jose Fire Station #18 would have access along the connector ramp. Skyway Drive Variant B would depress Monterey Road to connect to the Skyway Drive underpass. Under this variant, access to the mobile home park northwest of the intersection of Skyway Drive and Monterey Road would be provided by a driveway across the northern portion of the San Jose South Service Yard property. Variant B would not provide access to the fire station.

Continuing south, the HSR alignment would be at grade or on embankment between Monterey Road and UPRR for the remainder of the subsection. Branham Lane and Roeder Road/Chynoweth Avenue would be lowered to be separated from the HSR and existing railroad crossings. Because of the new grade difference between Branham Lane and Roeder Road/Chynoweth, access to Rice Way and four driveways from Monterey Road would be closed. A new Branham Lane pedestrian bridge would span the combined railroad and Monterey Road corridor. The westbound Blossom Hill Road ramp at Monterey Road would be shifted to the east side of Monterey Road. A new pedestrian bridge would be built to maintain connectivity between Ford Road and the Caltrain Blossom Hill Station. The alignment would continue south at grade under SR 85/West Valley Freeway, with modifications to the existing highway bridge to allow HSR to pass underneath. The alignment would then cross under Bernal Road before transitioning to the Morgan Hill and Gilroy Subsection at Bernal Way.

Like the other alternatives, the design assumes a reduction from six to four travel lanes on Monterey Road, beginning north of Capitol Expressway and continuing to just south of Blossom Hill Road, where the existing roadway is already four travel lanes. Under Alternative 2, one left turn lane would be removed south of Senter Street and one left turn lane would be removed south of Roeder where Monterey Road would be depressed and grade separated from adjacent properties. Existing mid-block left-turn lanes would be closed because of substandard stopping sight distance. Alternative 2 (and Alternative 4) differs from Alternatives 1 and 3 by shifting all Monterey Road travel lanes and median to the east of their current locations.

Wildlife Crossings

There would be no wildlife crossings in this subsection.

Stations

No new HSR stations are proposed for this subsection.

Traction Power Facilities

In the Monterey Corridor Subsection, traction power stations would be in the same area under Alternatives 1, 2 and 3. Traction power paralleling stations would be constructed at the following locations:

- Either the north side of the alignment near Curtner Avenue or the south side of the alignment at Communications Hill (same as Alternative 1)
- Either the south side of SR 85 or between Bernal Road and the Bernal Road ramp onto Monterey Road

Train Control and Communication Facilities

Train control and communication facilities under Alternative 2 would be the same as described for Alternative 1.

Maintenance Facilities

No maintenance facilities are proposed for this subsection.

2.2.2.3 Morgan Hill and Gilroy Subsection

Alignment and Ancillary Features

The Morgan Hill and Gilroy Subsection under Alternative 2 would be approximately 31 miles long and located south of the Monterey Corridor Subsection. From Bernal Way in South San Jose, the alignment would extend through Morgan Hill and San Martin to the Downtown Gilroy Station, then curve generally eastward across the Pajaro River floodplain and through a portion of northern San Benito County before entering a tunnel (Tunnel 1) at the base of the Diablo Range. The alignment would exit the tunnel at Casa de Fruta Parkway/SR 152 in unincorporated eastern Santa Clara County, and then transition to the Pacheco Pass Subsection (Figure 2-8).

Continuing from the southern limit of the Monterey Corridor Subsection, Alternative 2 would be at grade on retained fill between the UPRR right-of-way and Monterey Road in South San Jose. Due to the proximity of the alignment to UPRR, a 3-foot-thick continuous intrusion barrier would be constructed between the proposed HSR and UPRR tracks. In contrast to the other alternatives, Alternative 2 would require the construction of new roadway grade separations to maintain east-west connectivity across the Monterey Corridor. Before turning south near Kittery Court, the two UPRR tracks would be realigned to the west to accommodate the alignment curvature required for HSR operations until returning to the existing alignment adjacent to the south side of the Calpine Metcalf Energy Center. The existing Fisher Creek culvert would be improved with a new culvert installed beneath the new HSR alignment and realigned Monterey Road and UPRR. The creek crossing would be improved to provide a suitable wildlife crossing. The Blanchard Road grade crossing would be closed.

As the UPRR and Monterey Road rights-of-way converge to the south approaching Bailey Avenue, the four-lane Monterey Road would be realigned eastward to accommodate the HSR alignment at grade between the railroad and roadway. The existing Bailey Avenue bridge would remain in place and HSR would cross beneath the road. The alignment would continue south, ascending onto embankment, crossing beneath a new Palm Avenue bridge and a new Live Oak Avenue bridge (which would also cross over UPRR, eliminating both existing at-grade crossings). Tilton Avenue would become a cul-de-sac. Madrone Parkway would be lowered to allow HSR and UPRR to cross over the roadway. At Cochrane Road, the realigned Monterey Road would converge with the existing roadway alignment.

As the alignment proceeds south along the UPRR alignment through Morgan Hill, a new culvert would be placed in the HSR embankment for Fisher Creek. The alignment would then cross over Monterey Road on a clear-span bridge. Continuing south on embankment along the east side of

UPRR, the HSR and UPRR alignments would cross over Main, East/West Dunne, San Pedro, and Tennant Avenues on short bridges over the roadways, which would be lowered 17–30 feet below grade to maintain east-west connections. A new pedestrian underpass would be provided to maintain access from east of the HSR corridor to the Morgan Hill Caltrain Station. Railroad Avenue would be closed between San Pedro Avenue and Barrett Avenue and relocated eastward between Barrett Avenue and Maple Avenue to accommodate the HSR alignment adjacent to UPRR. The existing bridge at Butterfield Boulevard would be extended to cross over the realigned Railroad Avenue and at-grade HSR alignment. The Butterfield Canal would be relocated to the east to accommodate the HSR alignment adjacent to UPRR.

Continuing south, the alignment would ascend onto embankment, and West Little Llagas Creek would flow through a new culvert. The existing East Middle Avenue would become cul-de-sacs on both sides of the alignment. A new alignment of East Middle Avenue would be constructed to the south, where it would cross over the HSR tracks and Monterey Road on a bridge. Monterey Road and UPRR would be realigned westward between East Middle Avenue and Roosevelt Avenue to accommodate the southward alignment curvature required for HSR operations. The realigned roadway and UPRR and the new HSR alignment would cross Llagas Creek on new clear-span bridges. South of Llagas Creek, Monterey Road would return to the existing alignment near Roosevelt Avenue.

San Martin Avenue would be realigned between Murphy and Harding Avenues to connect to Oak Street at Llagas Avenue (north of the HSR alignment) in San Martin. HSR would cross over San Martin Avenue and Oak Street, which would be below grade. A pedestrian path under the HSR embankment would be provided south to San Martin Avenue. Depot Street, UPRR, and Monterey Road, which parallel the HSR tracks at Oak Street, would cross the newly depressed San Martin (formerly Oak) Street on bridges supported by retained fill. HSR would continue south at grade adjacent to the east side of UPRR. Church Avenue would be raised onto a bridge over both HSR and UPRR. Fitzgerald and Masten Avenues would be realigned to the south and would be depressed beneath Monterey Road, UPRR, and HSR. Similarly, Rucker Avenue and Buena Vista Avenue would be depressed beneath Monterey Road, UPRR, and HSR. Both Cohansey Avenue and Las Animas Avenue would remain at grade with bridges for HSR and UPRR to cross over the existing streets.

Continuing south into Gilroy, the alignment would shift east for the approach to the Downtown Gilroy HSR Station. The existing culvert for the West Branch of Llagas Creek would be extended to the east to accommodate the rail alignment shift. HSR and UPRR would be on embankment (approximately 15–25 feet high) and cross over Leavesley Road, Casey Street, IOOF Avenue, Lewis Street, East 6th Street, and the realigned East 7th Street/Old Gilroy on bridges before arriving at the Downtown Gilroy Station embankment (approximately 16 feet high). East 7th Street and Old Gilroy would be realigned (as under Alternative 1). Each of these streets would be lowered approximately 20 feet beneath existing grade, and a pedestrian underpass would replace Martin Street across the rail alignment. Miller Slough would be realigned eastward in a new culvert beneath the railroad alignment. HSR and UPRR would continue on embankment, crossing over East 9th Street and East 10th Street.

The HSR alignment would continue on embankment south from the Downtown Gilroy Station to the Princevale Channel, then descend into a trench under Luchessa Avenue and US 101, where existing bridges would be demolished and reconstructed to accommodate the freeway undercrossing, and two UPRR spur tracks. Just south of the US 101 overcrossing, a freight connection would be made from UPRR on the south side of HSR, crossing over the HSR trench to connect to the South Gilroy MOWF on the north side of HSR. Two UPRR spur tracks would be realigned to connect to the MOWF freight track north of HSR.

The remainder of this subsection—to Casa de Fruta—would be the same as under Alternative 1.

Wildlife Crossings

Three adjacent box culverts would be installed to provide wildlife with a connection between Tulare Hill and Coyote Creek south of Metcalf Road. The box culverts under Monterey Road and

UPRR would be replaced with larger box culverts at Fisher Creek. HSR would also be on a box culvert over Fisher Creek. These three box culverts would have larger openings than existing culverts to improve wildlife movement. There would be seven additional crossings at Emado Avenue, Laguna Avenue, Richmond Avenue, Fox Lane, Paquita Espana Court, south of Palm Avenue, and south of Live Oak Avenue.

Stations

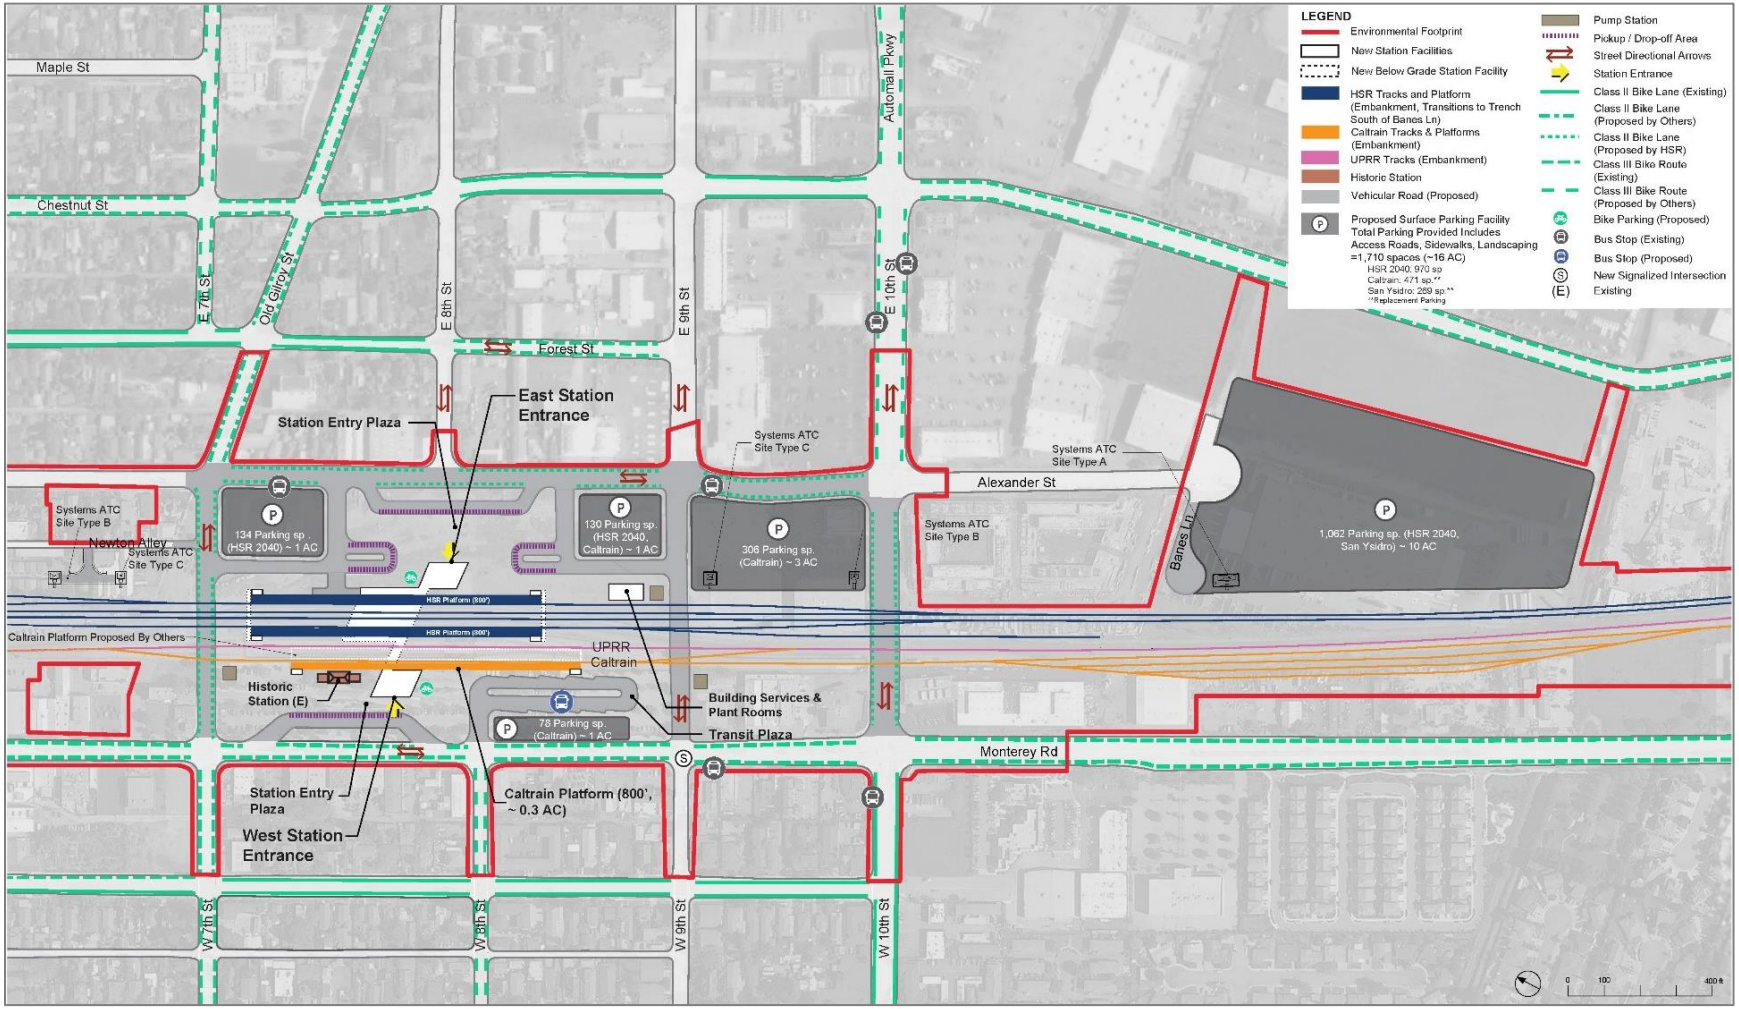
Alternative 2 would enter the Downtown Gilroy Station on embankment (Figures 2-14 and 2-15). The station layout and configuration would be similar to that described for Alternative 1, except that UPRR and Caltrain would be elevated to the same height as HSR on the embankment. The embankment station would also lower East 7th/Old Gilroy Street, East 9th Street, and East 10th Street by approximately 16 feet to maintain street access.

As under Alternative 1, the existing 471 Caltrain parking spaces on the west side of the station would be replaced 1:1 by either reconfiguring parking on the west side of the station or relocating it to the east side of the station. The existing 269 San Ysidro housing development parking spaces would be replaced 1:1 with new surface parking along Automall Parkway with access from the south end of Alexander Street. HSR would provide an additional 970 spaces in 2040, for a total of 1,710 parking spaces in 2040 (including existing demand). The station site plan provides 970 new parking spaces in five areas. One site would be located west of the station along Monterey Road at 9th Street. The other four would be on the east side of the station along Alexander Street at Old Gilroy Street, 9th Street, 10th Street, and Banes Lane. A multimodal access plan that includes a parking strategy would be developed in coordination with local agencies prior to design and construction of the station. A total of eight bus bays would be provided. Street improvements would include realignment of Old Gilroy Street at East 7th Street; existing grade crossings would remain unchanged. A 4,000-square-foot bicycle facility would be constructed. Class II bike lanes would be provided on 7th, Alexander, and 10th Streets.

Traction Power Facilities

As under Alternative 1, one new TPSS, Site 4—Gilroy, would be constructed at one of two alternate sites on the north side of the alignment: either east or west of Bloomfield Avenue. At this location, one new utility switching station would be co-located with the TPSS. Communication facilities (i.e., redundant [two underground or one underground and one overhead on existing power structures] fiber optic lines) would also be required to support the electrical interconnection of the TPSS to a new utility switching station or to existing PG&E facilities, typically within tie-line/utility corridors. Site 4—Gilroy would connect to the Llagas PG&E substation via existing and proposed transmission or distribution lines along SR 152, Frazier Lake Road, and Bloomfield Avenue. Fiber optic and high-voltage lines would be reconductored overhead on existing towers where available. Where no overhead connections exist, both fiber optic and high-voltage lines would be undergrounded within or adjacent to the public right-of-way.

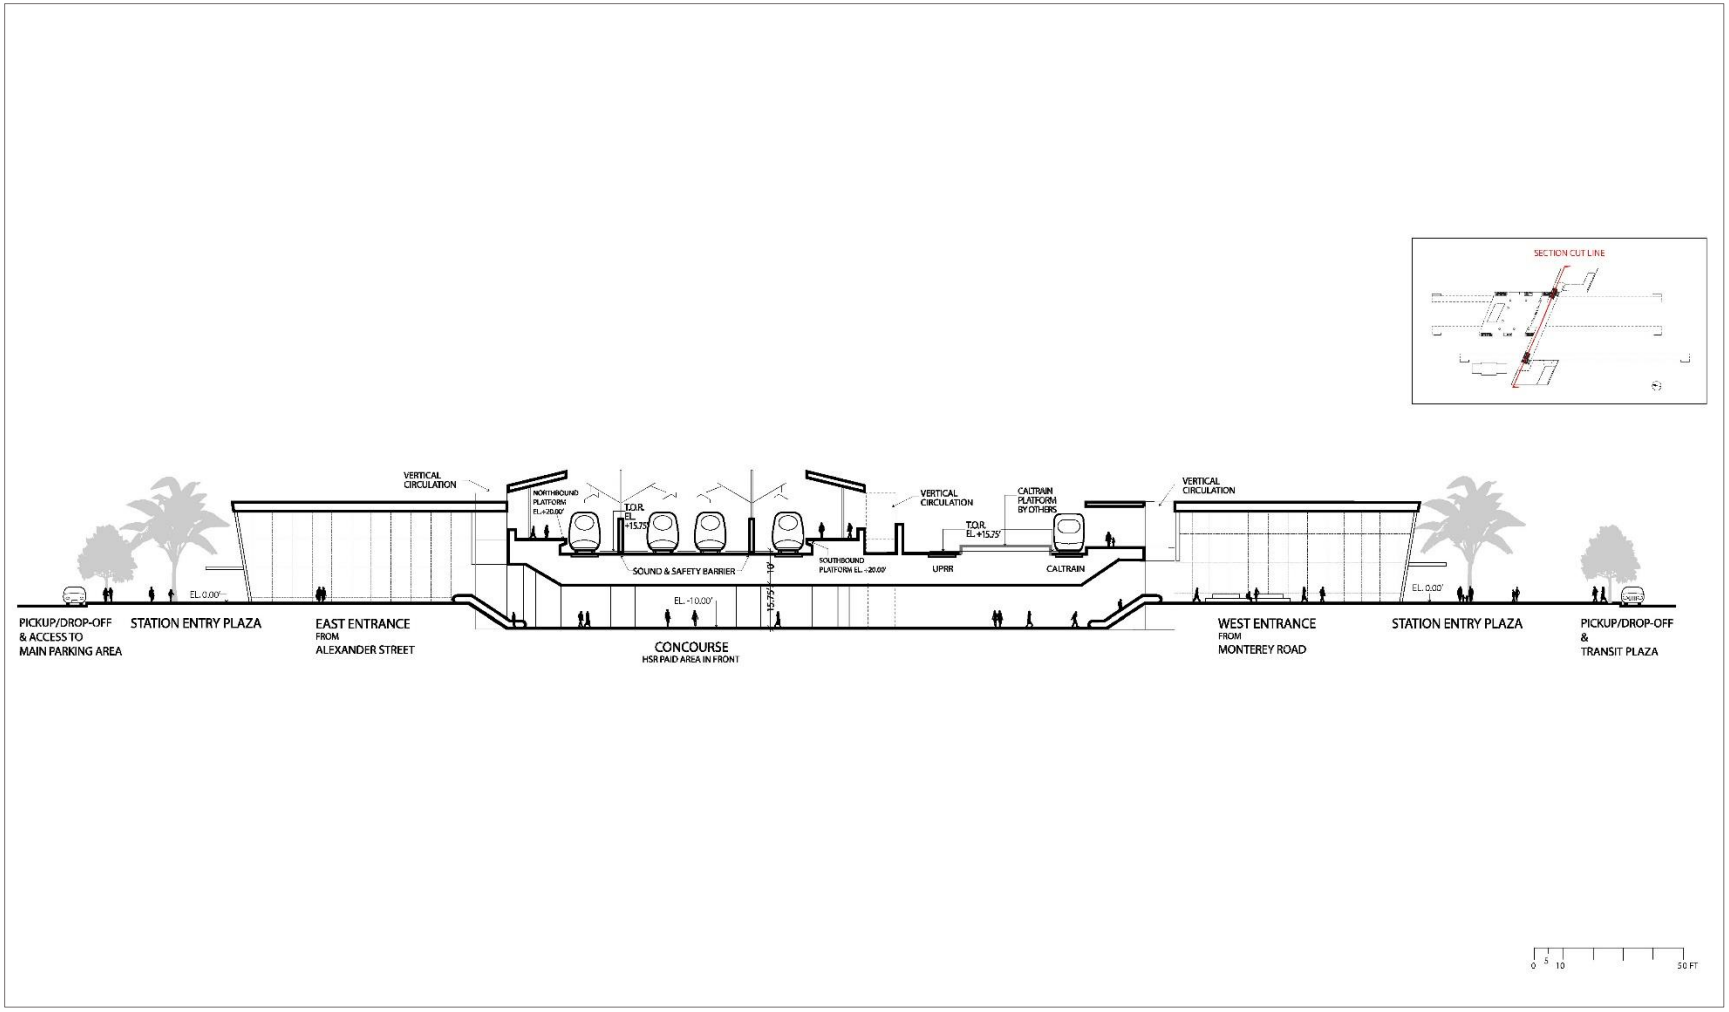
A traction power switching station would be constructed east of the HSR alignment at a location north of Paquita Espana Court or north of Palm Avenue.



Source: Authority 2019b

JUNE 2019

Figure 2-14 Conceptual Downtown Gilroy Embankment Station Plan



Source: Authority 2019b

JUNE 2019

Figure 2-15 Cross Section of Downtown Gilroy Station (Embankment)

Four traction power paralleling stations would be constructed at the following locations:

- Either the east side of the alignment between East Dunne and San Pedro Avenues or south of San Pedro Avenue
- East of the alignment, either north or south of a new Masten Avenue/Fitzgerald Avenue in-trench alignment

South of US 101, Alternative 2 would have the same two switching stations as Alternative 1:

- Either south of the alignment and west of Lovers Lane or north of the alignment and west of Lovers Lane
- In the vicinity of the Tunnel 1 east portal, either at the portal or east of SR 152 in the southern area of Casa de Fruta

PG&E would reinforce the electric power distribution network to meet HSR traction and distribution power requirements by replacing (reconductoring) the approximately 9.8-mile Metcalf to Morgan Hill and 10.6-mile Morgan Hill to Llagas 115-kV power lines. These PG&E transmission network upgrades described under Alternative 1 would also be necessary under Alternative 2.

Train Control and Communication Facilities

A total of 20 ATC sites would be constructed in the Morgan Hill and Gilroy Subsection for this alternative:

- One site east of Monterey Road north of Paquita Espana Court or at Palm Avenue, co-located with the TPSS (two site options)
- One site north of East Middle Avenue (two site options)
- One site between Las Animas Avenue and Leavesley Road
- One site south of Leavesley Road
- One site south of Lewis Street
- One site north of 6th Street in Gilroy
- Two sites south of 6th Street in Gilroy
- Two sites between 9th and 10th Streets in Gilroy
- One site south of Banes Lane

South of US 101, Alternative 2 would have the same ATC sites as Alternative 1:

- Five sites north of Carnadero Avenue
- Three sites east of the Pajaro River
- One site near Lake Road (two site options)

A total of six stand-alone communication radio sites would be constructed in this subsection at the following locations:

- Between Forsum Road and Blanchard Road (two site options)
- Near Bailey Avenue (two site options)
- Near Kirby Avenue (two site options)
- West of the intersection of Cochrane Road and Monterey Road (two site options)
- Near South Street (two site options)

South of US 101, Alternative 2 would have the same radio sites as Alternative 1:

- East of the Pajaro River south of Gilroy.

Maintenance Facilities

The MOWF under Alternative 2 would be constructed along the HSR alignment near Carnadero Avenue as described for Alternative 1 and illustrated on Figure 2-12. The freight connection would be provided as described above.

2.2.2.4 Pacheco Pass Subsection

Alignment and Ancillary Features

The characteristics of the Pacheco Pass Subsection under Alternative 2 would be the same as those described for Alternative 1 in Section 2.2.1.4, Pacheco Pass Subsection.

Wildlife Crossings

The wildlife crossings under Alternative 2 would be the same as described for Alternative 1.

Stations

No new HSR stations are proposed for this subsection.

Traction Power Facilities

One new TPSS, Site 5—O'Neill, would be constructed approximately 1.2 miles west of the California Aqueduct as described for Alternative 1.

Train Control and Communication Facilities

Train control and communications facilities of Alternative 2 would be the same as for Alternative 1.

Maintenance Facilities

No maintenance facilities are proposed for this subsection.

2.2.2.5 San Joaquin Valley Subsection

Alignment and Ancillary Features

The characteristics of the San Joaquin Valley Subsection of Alternative 2 would be the same as those described for Alternative 1 in Section 2.2.1.5, San Joaquin Valley Subsection.

Wildlife Crossings

The wildlife crossings under Alternative 2 would be as described for Alternative 1.

Stations

No new HSR stations are proposed for this subsection.

Traction Power Facilities

Traction power facilities under Alternative 2 would be as described for Alternative 1.

Train Control and Communication Facilities

Train control and communications facilities of Alternative 2 would be as described for Alternative 1.

Maintenance Facilities

An MOWS would be constructed near Turner Island Road near Carlucci Road as described for Alternative 1 and illustrated on Figure 2-15.

2.2.3 Alternative 3

Alternative 3 was designed to minimize the project footprint through the use of viaduct and by going around downtown Morgan Hill, as is proposed in Alternative 1. Alternative 3 would bypass downtown Gilroy to an East Gilroy Station, further minimizing interface with the UPRR corridor in

comparison to Alternative 1. The HSR guideway under this alternative would comprise 43.2 miles on viaduct, 1.8 miles at grade, 24.9 miles on embankment, 2.4 miles in trench, and two tunnels totaling 15.0 miles.

2.2.3.1 San Jose Diridon Station Approach Subsection

Alignment and Ancillary Features

Under Alternative 3, the alignment and characteristics of this subsection would be the same as described for Alternative 2 in Section 2.2.2.1, San Jose Diridon Station Approach Subsection.

Wildlife Crossings

As under Alternative 2, there would be no wildlife crossings in this subsection.

Stations

The San Jose Diridon Station would be as described for Alternatives 1 and 2.

Traction Power Facilities

Traction power facilities under Alternative 3 would be as described for Alternative 2.

Train Control and Communication Facilities

Train control and communications facilities of Alternative 3 would be as described for Alternative 2. No stand-alone communication radio antenna would be constructed in this subsection of Alternative 3.

Maintenance Facilities

No maintenance facilities are proposed for this subsection.

2.2.3.2 Monterey Corridor Subsection

Alignment and Ancillary Features

The alignment and characteristics of Alternative 3 in this subsection would the same as those described for Alternative 1 in Section 2.2.1.2, Monterey Corridor Subsection.

Wildlife Crossings

As under Alternative 1, there would be no wildlife crossings in this subsection.

Stations

No new HSR stations are proposed for this subsection.

Traction Power Facilities

Traction power facilities of Alternative 3 would be as described for Alternative 1.

Train Control and Communication Facilities

Train control and communications facilities of Alternative 3 would be as described for Alternative 1 and Alternative 2.

Maintenance Facilities

No maintenance facilities are proposed for this subsection.

2.2.3.3 Morgan Hill and Gilroy Subsection

Alignment and Ancillary Features

The Morgan Hill and Gilroy Subsection under Alternative 3 would be approximately 30 miles long and located south of the Monterey Corridor Subsection. From Bernal Way in South San Jose, the alignment through Morgan Hill and San Martin would be the same as described for Alternative 1 in Section 2.2.1.3, Morgan Hill and Gilroy Subsection. The Alternative 3 alignment would diverge

from Alternative 1 by turning east north of Gilroy to arrive at the East Gilroy Station and an MOWF near SR 152. South of the MOWF, the alignment would curve generally east across the Pajaro River floodplain and through a portion of northern San Benito County before entering a tunnel (Tunnel 1) at the base of the Diablo Range. The Morgan Hill and Gilroy Subsection would end in the Pacheco Pass at Casa de Fruta Parkway/SR 152 (Figure 2-8), where the Alternative 3 alignment would converge with that of Alternatives 1 and 2.

South of the Monterey Corridor Subsection, Alternative 3 would diverge east from Alternative 1 north of Gilroy, near the intersection of Monterey Road and Church Avenue. Beginning at Church Avenue, a new freight track would diverge from the UPRR mainline to provide a freight connection to the MOWF. The freight track would continue parallel to the HSR alignment on the west side to the MOWF. The HSR alignment would cross over Church Avenue, Lena Avenue, Masten Avenue, and US 101 at Rucker Avenue on viaduct approximately 60 feet above grade. The aerial alignment would also cross over Denio Avenue and Buena Vista Avenue on viaduct before descending onto embankment. Cohansey Avenue would be closed. At the north end of the East Gilroy Station site, the alignment would cross beneath Las Animas Avenue; at the south end of the station site, Leavesley Road would be raised on a bridge over the HSR embankment. At the south end of the East Gilroy Station site, the Llagas Creek overbank flow would be directed across the HSR alignment through two culvert crossings. Farther southeast, the alignment would cross over Gilman Avenue on viaduct. The alignment would cross Llagas Creek on a low viaduct, and Holsclaw Road would be closed to vehicular traffic. Levee Road would be realigned south of Llagas Creek.

Continuing south, the alignment would ascend to approximately 25 feet above grade on embankment approaching the MOWF site. SR 152 would be grade separated and realigned, crossing over the MOWF on a bridge. Both Frazier Lake Road and Holsclaw Road would connect to the grade-separated SR 152. The MOWF, on the south side of the alignment, would have the same features as the MOWF under Alternatives 1 and 2 and would similarly be on an embankment. Additional flood detention basins would be installed around the eastern edge of the MOWF to provide sufficient flood capacity in the Soap Lake floodplain. Jones Creek would be realigned around the eastern boundary of the MOWF, crossing beneath the HSR viaduct over Bloomfield Avenue. Continuing on a 40-foot-high embankment and then on viaduct, the alignment would cross the Pajaro River, Millers Canal, Lake Road, Pacheco Creek, Lovers Lane, San Felipe Road, and SR 152 before entering the west portal of Tunnel 1. Tequisquita Slough would be partially filled by the HSR embankment, which would include cross-culverts, 3.1 acres of adjacent floodwater detention basins, and extended viaduct over Pacheco Creek to maintain floodplain capacity and function.

The Alternative 3 alignment would converge at Tunnel 1 with those of the other alternatives.

Wildlife Crossings

Wildlife crossings would be provided between Bernal Way and San Martin as described for Alternative 1 with crossings at Tulare Hill, Fisher Creek, and Llagas Creek. Although Alternative 3 would include more embankment than Alternative 1, it would be similar to Alternative 1 by continuing primarily on viaduct through the Soap Lake area to allow for wildlife movement.

Stations

Alternative 3 would enter the East Gilroy Station on embankment (approximately 17 feet to top of rail) north of Leavesley Road (Figures 2-16 and 2-17). The station platforms would be 800 feet long and the station buildings would be constructed on both the east and west sides of the tracks with a connections concourse under the tracks. The MOWF freight access track would continue through the station on the west side of the west station platform. Access for passengers arriving by auto would be available from either the east or west entrance, while the main entrance on the west side would also provide access for passengers arriving by transit or bicycle. The HSR station buildings would encompass 58,611 square feet with a 4,400-square-foot substation and systems building. The concourse would be below the tracks and embankment. Approximately 1,520 on-site parking spaces would be provided to meet the projected demand in 2040. Spaces would be located on the east and west sides of the building. The west side station parking would

be accessed from Leavesley Road and a new station access road east of the outlet mall. The east side station parking would be accessed from Marcella Avenue. A multimodal access plan would be developed prior to design and construction of the station.

Seven bus bays would be provided on site on the west side of the station. A 4,000-square-foot bicycle parking facility would be constructed; a new Class III bike route would be provided from the outlet mall to the site entrance; then Class II lanes from the station entrance to the parking. Class I bidirectional off-street path would be provided adjacent to parking which connects to the bike station. This would be a new station without any other rail operators in the station area.

Traction Power Facilities

Under Alternative 3, one new TPSS, Site 4—Gilroy, would be constructed at one of two sites: north of HSR either east or west of the former SR 152. Communication facilities (i.e., redundant [two underground or one underground and one overhead on existing power structures] fiber optic lines) would also be required to support the electrical interconnection of the TPSS to a new utility switching station and/or to existing PG&E facilities, typically within tie-line/utility corridors.

As under Alternative 1, a traction power switching station would be constructed at one of two locations north of Palm Avenue and east of the alignment.

Four traction power paralleling stations would be constructed at the following locations:

- South of the alignment, located either south of Diana Avenue or at the intersection of San Pedro Avenue and Walnut Grove Drive (like Alternative 1)
- Either at the northwest or southeast corner of the HSR crossing of Masten Avenue
- South of Gilroy at one of three site options: on Lake Road north of the alignment, on Lake Road south of the alignment, or at Lovers Lane south of the alignment
- Near the Tunnel 1 east portal, either at the portal or east of SR 152 in the southern area of Casa de Fruta

The PG&E transmission network upgrades from Metcalf to Morgan Hill and from Morgan Hill to Llagas described for Alternative 1 would also be necessary under Alternative 3. In addition to a new utility switching station co-located with the TPSS, a tie-line route and power distribution to the Tunnel 1 portal under this alternative would be the same, albeit with shorter electrical line routes, as those described for Alternative 1. A distribution power line for the Tunnel 1 portals would be constructed on the south side of the alignment northeast of the intersection of Walnut Lane and SR 152, crossing over and connecting with the TPSS from the north. One power drop site would be provided at the east and west portals (two options for each portal location).

Train Control and Communication Facilities

A total of 19 ATC sites would be constructed in the Morgan Hill and Gilroy Subsection for this alternative:

- One site east of Monterey Road near Palm Avenue (two site options)
- One site near East Middle Avenue (two site options)
- Two sites near Cohansey Way
- Four sites between Las Animas Avenue and Leavesley Road
- Three sites south of Leavesley Road
- Four sites north of SR 152, east of Gilroy
- Two sites within the MOWF
- Three sites north of Bloomfield Avenue
- One site near Lake Road (two site options)

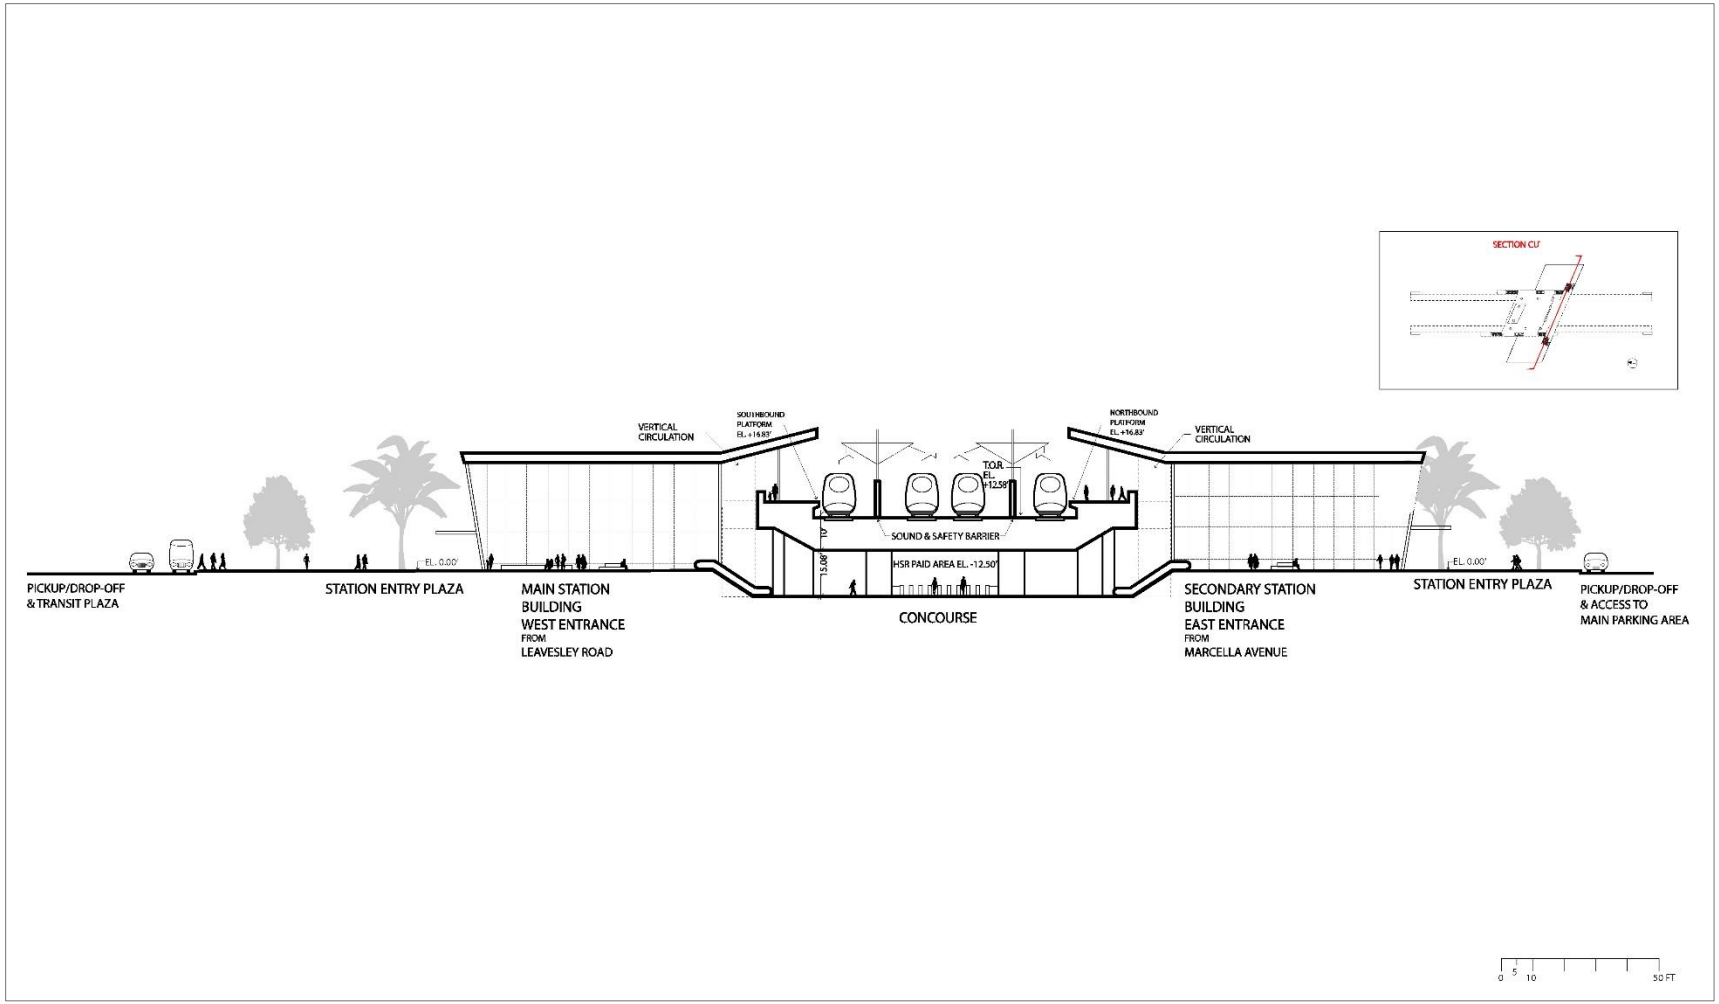
JUNE 2019

Figure 2-16 Conceptual East Gilroy Station Plan



Source: Authority 2019b

JUNE 2019

Figure 2-17 Cross Section of East Gilroy Station

A total of six stand-alone communication radio sites would be constructed in this subsection (five locations are the same as those for Alternative 1):

- Between Barnhart Avenue and Kirby Avenue (two site options)
- South of Cochrane Road along US 101 (two site options)
- North of Cox Avenue and south of West San Martin Avenue (two site options)
- At Bloomfield Avenue

Maintenance Facilities

The East Gilroy MOWF would be located west of the HSR mainline, south of the community of Old Gilroy. The MOWF would encompass approximately 75 acres and extend along the west side of the HSR alignment from the intersection of the SR 152 and Frazer Lake Road south to Jones Creek (Figure 2-18). The freight connection would be provided as described in the discussion of the alignment and ancillary facilities.

2.2.3.4 Pacheco Pass Subsection

Alignment and Ancillary Features

The characteristics of the Pacheco Pass Subsection of Alternative 3 would be the same as Alternatives 1 and 2.

Wildlife Crossings

The wildlife crossings under Alternative 3 would be as described under Alternative 1.

Stations

No new HSR stations are proposed for this subsection.

Traction Power Facilities

Traction power facilities of Alternative 3 would be as described for Alternatives 1 and 2.

Train Control and Communication Facilities

Train control and communications facilities of Alternative 3 would be as described for Alternatives 1 and 2.

Maintenance Facilities

No maintenance facilities are proposed for this subsection.

2.2.3.5 San Joaquin Valley Subsection

Alignment and Ancillary Features

The characteristics of the San Joaquin Valley Subsection under Alternative 3 would be the same as under Alternatives 1 and 2.

Wildlife Crossings

The wildlife crossings under Alternative 3 would be as described for Alternatives 1 and 2.

Stations

No new HSR stations are proposed for this subsection.

Traction Power Facilities

Traction power facilities of Alternative 3 would be as described for Alternatives 1 and 2.

Train Control and Communication Facilities

Train control and communications facilities would be as described for Alternatives 1 and 2.

.

JUNE 2019

Figure 2-18 East Gilroy Maintenance of Way Facility

Maintenance Facilities

An MOWS would be constructed near Turner Island Road near Carlucci Road as described for Alternatives 1 and 2 (Figure 2-13)

2.2.4 Alternative 4 (State's Preferred Alternative, CEQA Proposed Project)

On September 17, 2019, the Authority Board of Directors reviewed a staff recommendation on the State's Preferred Alternative and a summary of key identified outreach concerns. The Board confirmed that Alternative 4 is the State's Preferred Alternative for purposes of the Draft EIR/EIS and serves as the CEQA proposed project for purposes of State CEQA Guidelines Section 15124.

The process for considering and the rationale for selecting the State's Preferred Alternative are presented in Chapter 8, Preferred Alternative, of the Final EIR/EIS.

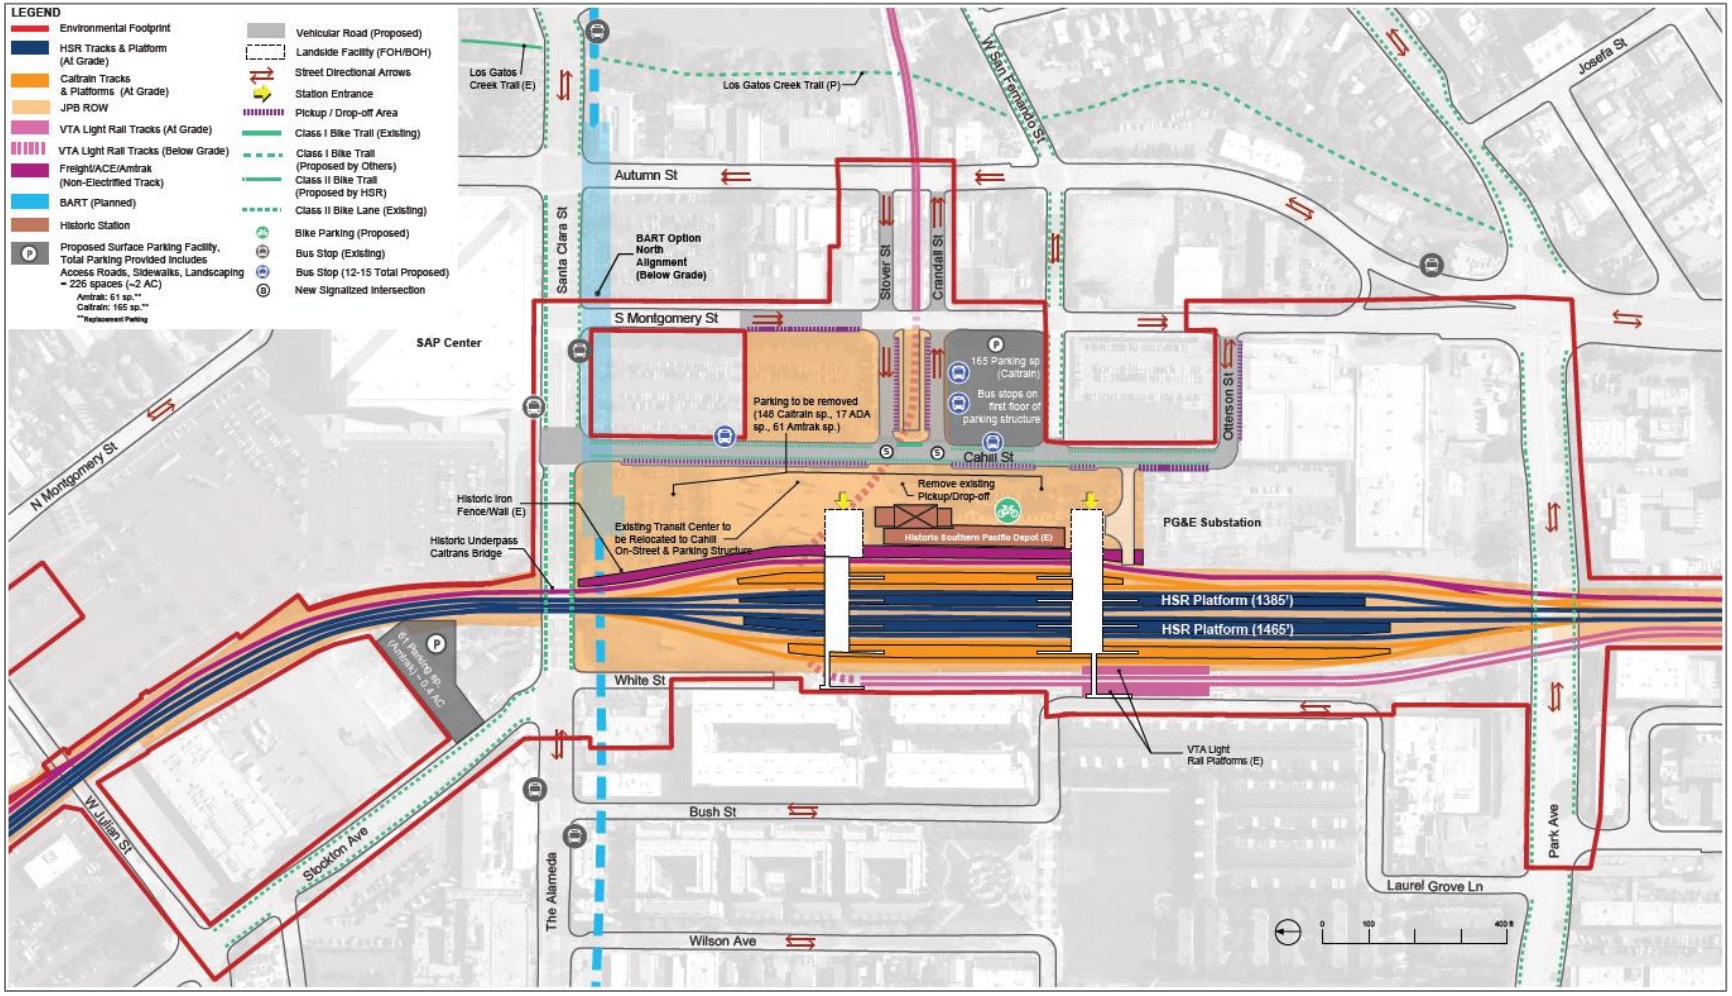
Development of Alternative 4 was intended to extend blended electric-powered passenger railroad infrastructure from the southern limit of the Caltrain Peninsula Corridor Electrification Project through Gilroy. South and east of Gilroy, HSR would operate in a dedicated guideway similar to Alternatives 1, 2, and 3. The objectives of this approach are to minimize property displacements and natural resource impacts, retain local community development patterns, improve the operational efficiency and safety of the existing railroad corridor, and accelerate delivery of electrified passenger rail services in the increasingly congested southern Santa Clara Valley corridor. The alternative is distinguished from the three other project alternatives by a blended, at-grade alignment that would operate on two electrified passenger tracks and one conventional freight track predominantly within the existing Caltrain and UPRR rights-of-way. The maximum train speed of 110 mph in the blended guideway would be enabled by continuous access-restriction fencing; four-quadrant gates, roadway lane channels, and railroad trespass deterrents at all public road grade crossings; and fully integrated communications and controls for train operations, grade crossings, and roadway traffic. Caltrain stations would be reconstructed to enable directional running as part of blended operations. Overall, this alternative would be comprised of 15.2 miles on viaduct, 30.3 miles at grade, 25.9 miles on embankment, 2.3 miles in trench, and two tunnels with a combined length of 15.0 miles.

2.2.4.1 San Jose Diridon Station Approach Subsection

Alignment and Ancillary Features

Alternative 4 would begin at Scott Boulevard in blended service with Caltrain on an at-grade profile following Caltrain MT2 and MT3 south along the east side of the existing Caltrain corridor. The existing Lafayette Street pedestrian overpass would remain in place, as would the De La Cruz Boulevard and West Hedding Street roadway overpasses. New UPRR track would start just south of Emory Street to maintain freight movement capacity north of San Jose Diridon Station. The new UPRR track would be east of Caltrain MT1. The existing College Park Caltrain Station would be reconstructed just north of Emory Street on the west side of the Caltrain Corridor on the existing siding track to eliminate the existing holdout rule at the station. A portion of both legs of the UPRR Warm Springs Subdivision Lenzen Wye would undergo minor track adjustments, and a new bridge would be built over Taylor Street for UPRR to tie into the Lenzen Wye.

The blended at-grade alignment would continue along MT2 and MT3 to enter new dedicated HSR platforms at grade at the center of San Jose Diridon Station (Figure 2-19). HSR platforms would be extended south to provide 1,385-foot and 1,465-foot platforms and would be raised to provide level boarding with the HSR trains. The existing Santa Clara Street underpass would remain, but the track in the throat and yard would require modification. There would be no need for modifications to the VTA light rail.



Source: Authority 2019b

JUNE 2019

Figure 2-19 Conceptual San Jose Diridon At-Grade Station Plan

Continuing south, the blended at-grade three-track alignment would remain in the Caltrain right-of-way through the Gardner neighborhood. The existing underpass at Park Avenue and the existing overpass at San Carlos Street would remain in place. Four-quadrant gates with channelization would be built at Auzerais Avenue and West Virginia Street. A new bridge for the blended HSR/MT3 track over I-280 would be constructed. The existing underpasses at Bird Avenue and Delmas Avenue would be reconstructed, as would the rail bridge overpasses. New standalone rail bridges over Prevost Street, SR 87, the Guadalupe River, and Willow Street would be built for MT3. MT1 and MT2 would remain on the existing structures. The existing Tamien Caltrain Station would remain in place.

Wildlife Crossings

There would be no wildlife crossings in this subsection.

Stations

The San Jose Diridon Station would entail a four-track at-grade alignment through the center of the existing Diridon station, with 1,385- and 1,465-foot platforms centered between Santa Clara Street and Park Avenue (Figure 2-19). The existing historic train station would remain in place. A pedestrian concourse would be built above the yard to provide access to the platforms below. The concourse would consist of a pedestrian walkway above the existing Caltrain tracks and below the HSR platforms, with two entrances on the east side and one on the west.

Construction of San Jose Diridon Station would require displacement of 226 parking spaces. These would be replaced 1:1 in a parking structure at Cahill/Crandall Streets and a second site at Stockton/Alameda Streets. The existing on-site/off-street bus transit center would be relocated to an off-street facility between Cahill, Crandall, South Montgomery, and West San Fernando Streets. Street improvements would include reconfiguring and extending Cahill Street from Santa Clara Street to Otterson Street and extending Stover and Crandall Streets to South Montgomery Street. New bike lanes would be installed on the east side of Cahill Street. New signals and pedestrian crossings would be developed at Cahill and Stover Streets and Cahill and Crandall Streets.

Phasing for interim operations (2027) includes a pedestrian overhead crossing (PED OC) south of the existing historic station and would provide circulation access from the PED OC only to HSR platforms. Caltrain would continue to use the existing tunnel for access. Phasing for Valley-to-Valley (2029) includes access to and from all Caltrain and HSR platforms. At this stage, the existing tunnel would be used only for exiting purposes on HSR platforms. At buildout, there would be an additional PED OC north of the historic station with access to all Caltrain and HSR platforms. From the HSR platforms, the existing tunnel would continue to be used only for exiting.

Train Control and Communication Facilities

Under Alternative 4, HSR would use the existing ATC sites included as part of the Caltrain Positive Control and Electrification Project.

One stand-alone communications radio site would be constructed at one of two locations, both south of Scott Boulevard along the east side of the Caltrain corridor.

Maintenance Facilities

No maintenance facilities are proposed within this subsection.

2.2.4.2 Monterey Corridor Subsection

Alignment and Ancillary Features

The Monterey Corridor Subsection would be approximately 9 miles long and entirely within the San Jose city limits. From the San Jose Diridon Station Approach at West Alma Avenue, just south of the Caltrain Tamien Station, the alignment would extend primarily southeast to Bernal Way (Figure 2-4). Unlike Alternatives 1, 2, and 3, Alternative 4 would be in blended service with Caltrain on an at-grade profile within the Caltrain and UPRR right-of-way. HSR and Caltrain

would operate on the electrified MT2 and MT3 tracks, while UPRR would operate on a nonelectrified MT1. The two existing tracks would be shifted to accommodate the third track. The existing Tamien Caltrain Station would remain in place with two new electrified turnback tracks constructed south of the station to facilitate turning trains outside the station platform areas. The Michael Yard would be reconfigured to a double-ended facility to accommodate storage of Altamont Corridor Express trains and relocated to the east side of the corridor. A new standalone bridge over West Alma Avenue would be constructed for MT3 and a maintenance track, with MT1 and 2 remaining on the existing structure. A new bridge over Almaden Road would be constructed for MT2 and MT3, while MT1 would remain on the existing structures. The existing pedestrian overpass at Communications Hill would remain in place. Capitol Caltrain Station would be reconstructed with a new center platform between MT2 and MT3. The platform would be reached by a new pedestrian overpass built at the north end of the platform. The existing Capitol Expressway overpass would remain in place. Four-quadrant barrier gates with channelization would be built at Skyway Drive, Branhan Lane, and Chynoweth Avenue. The existing Blossom Hill Road overpass and adjacent pedestrian overpass would remain in place. The Blossom Hill Caltrain Station would be reconstructed; the existing pedestrian overpass and platform would be removed and a new center platform constructed between MT2 and MT3. The platform would be reached by a new pedestrian overpass built at the south end of the platform. Great Oaks Parkway would be realigned for approximately 1,350 feet to accommodate the widened rail corridor. SR 85 and Bernal Road overpasses would remain in place.

Wildlife Crossings

There would be no wildlife crossings in this subsection.

Stations

There would be no HSR stations within this subsection.

Traction Power Facilities

One traction power paralleling station would be built on the west side of the Caltrain Corridor near the Blossom Hill Caltrain Station.

Train Control and Communication Facilities

Five ATC sites would be built in the subsection:

- Near Communications Hill on the east side of the Caltrain corridor near Chateau La Salle Drive
- Near Communications Hill on the east side of the Caltrain corridor near Montecito Vista Way
- Near Communications Hill on the east side of the Caltrain corridor near Chateau La Salle Drive or Montecito Vista Way (two site options)
- Near Monterey Road on the west side of the Caltrain corridor near Capitol Caltrain Station
- Near Skyway Drive on the west side of the Caltrain corridor (two site options)
- Near Branham Lane on the west side of the Caltrain corridor

Two stand-alone communications radio sites built:

- Near Almaden Road on the east side of the Caltrain corridor
- Near Branham Lane on the west side of the Caltrain corridor

PTC sites would be constructed at the following locations:

- Two sites south of Almaden Road
- One site north of Capitol Caltrain Station
- One site co-located with the ATC site at Branham Lane

2.2.4.3 Morgan Hill and Gilroy Subsection

Alignment and Ancillary Features

The Morgan Hill and Gilroy Subsection under Alternative 4 would be approximately 32 miles long, continuing south from the Monterey Corridor Subsection. From Bernal Way in South San Jose, the alignment would extend through Morgan Hill and San Martin to the Downtown Gilroy Station, then curve generally east across the Pajaro River floodplain and through a portion of northern San Benito County before entering Tunnel 1 at the base of the Diablo Range. The alignment would exit the tunnel at Casa de Fruta Parkway/SR 152 in unincorporated eastern Santa Clara County, where it would transition to the Pacheco Pass Subsection. This subsection under Alternative 4 would be blended service with Caltrain on an at-grade profile within the Caltrain and UPRR right-of-way with an at-grade Downtown Gilroy Station. Past the Downtown Gilroy Station and south of the US 101 overpass, HSR would enter the fully grade-separated, dedicated track needed to operate HSR trains at speeds faster than 125 mph.

Beginning at the southern limit of the Monterey Corridor Subsection, the alignment would continue in blended service with Caltrain on an at-grade profile in the existing UPRR right-of-way. HSR and Caltrain would operate on the electrified MT2 and MT3 tracks, while UPRR would operate on MT1. A UPRR siding track would be provided between Blanchard Road and Bailey Avenue. Four-quadrant barrier gates would be installed at all existing public road crossings. Intrusion deterrents would be installed at all at-grade crossings. Three private roads crossing would be eliminated and alternate access provided to those properties. The existing Bailey Avenue overpass would remain in place. Under Alternative 4 the Monterey Road underpass would be reconstructed to accommodate the future widening of Monterey Road to four lanes. The Morgan Hill Caltrain Station would be reconstructed with two new side platforms built outside MT2 and MT3. The platform would be reached by a new pedestrian underpass constructed at the north end of the platform. The existing Butterfield Boulevard overpass would remain in place. Upper Llagas Creek bridge would be reconstructed.

The San Martin Caltrain Station would be reconstructed—the existing platform would be removed and a new center platform would be built between MT2 and MT3. The platform would be reached by a new pedestrian overpass constructed at the south end of the platform. The existing bridge at Miller Slough would be replaced with a triple-cell box. Blended service would end just south of the Downtown Gilroy Station, where Caltrain would have access to turn back and stabling tracks relocated from the station area to south of 10th Street on the west side of the UPRR right-of-way. The Gilroy Caltrain Station would be reconstructed—the existing Caltrain platform would be shifted south and served by a southbound station track. A northbound Caltrain side platform would be provided to the east of a northbound station track. Two side platforms would be provided for HSR on the outside of the MT2 and MT3 tracks. The platforms would be reached by a new pedestrian overpass constructed over the center of the platforms. HSR would continue south under the US 101 overpass, which would remain in place. Past the Industry spur, HSR would ascend onto embankment and then a bridge over the UPRR. Two bridges would be constructed, one for MT2 and MT3 and a separate one for the MOWF lead track. The UPRR Hollister branch line would be realigned to the west to accommodate HSR bridging over the UPRR tracks at a single location. HSR MT2 and MT3 would descend from the embankment before crossing over Bloomfield Road on a new structure. Four-quadrant barrier gates and intrusion deterrents would be installed at Bloomfield Road for the MOWF lead track and UPRR service track. HSR would continue past the MOWF and transition to a new viaduct structure to cross over Pajaro Creek. Continuing on viaduct until just west of Millers Canal, Alternative 4 would join Alternative 1 as described for Alternative 1.

Wildlife Crossings

Twelve wildlife crossings or jump-outs would be built in this subsection:

- Three adjacent wildlife crossings with jump-outs integrated into the wing walls at Tulare Hill

- Fisher Creek culvert under UPRR and Monterey Road replaced with a larger box culvert to improve wildlife crossing potential at this location
- Wildlife crossings and integrated jump-outs south of Emado Avenue, south of Fisher Road, and south of Live Oak
- Wildlife crossings at Richmond Avenue, Paquita Espana Court, and north of Kalana Avenue
- Dedicated jump-outs north of Fisher Creek, south of Blanchard Road, north of Kalana Avenue, and at Miramonte Avenue

Wildlife intrusion deterrents would be constructed for at-grade crossings at Blanchard Road, Palm Avenue, Live Oak Avenue, and Bloomfield Road.

Stations

The Downtown Gilroy Station approach would be at grade with dedicated HSR tracks to the west of UPRR between Old Gilroy Street/7th Street, which would be closed, and 9th Street (Figure 2-20). A new HSR station with 800-foot platforms would be built south of the existing Caltrain station. A pedestrian concourse would be built above the UPRR and Caltrain tracks to provide access to the platforms below.

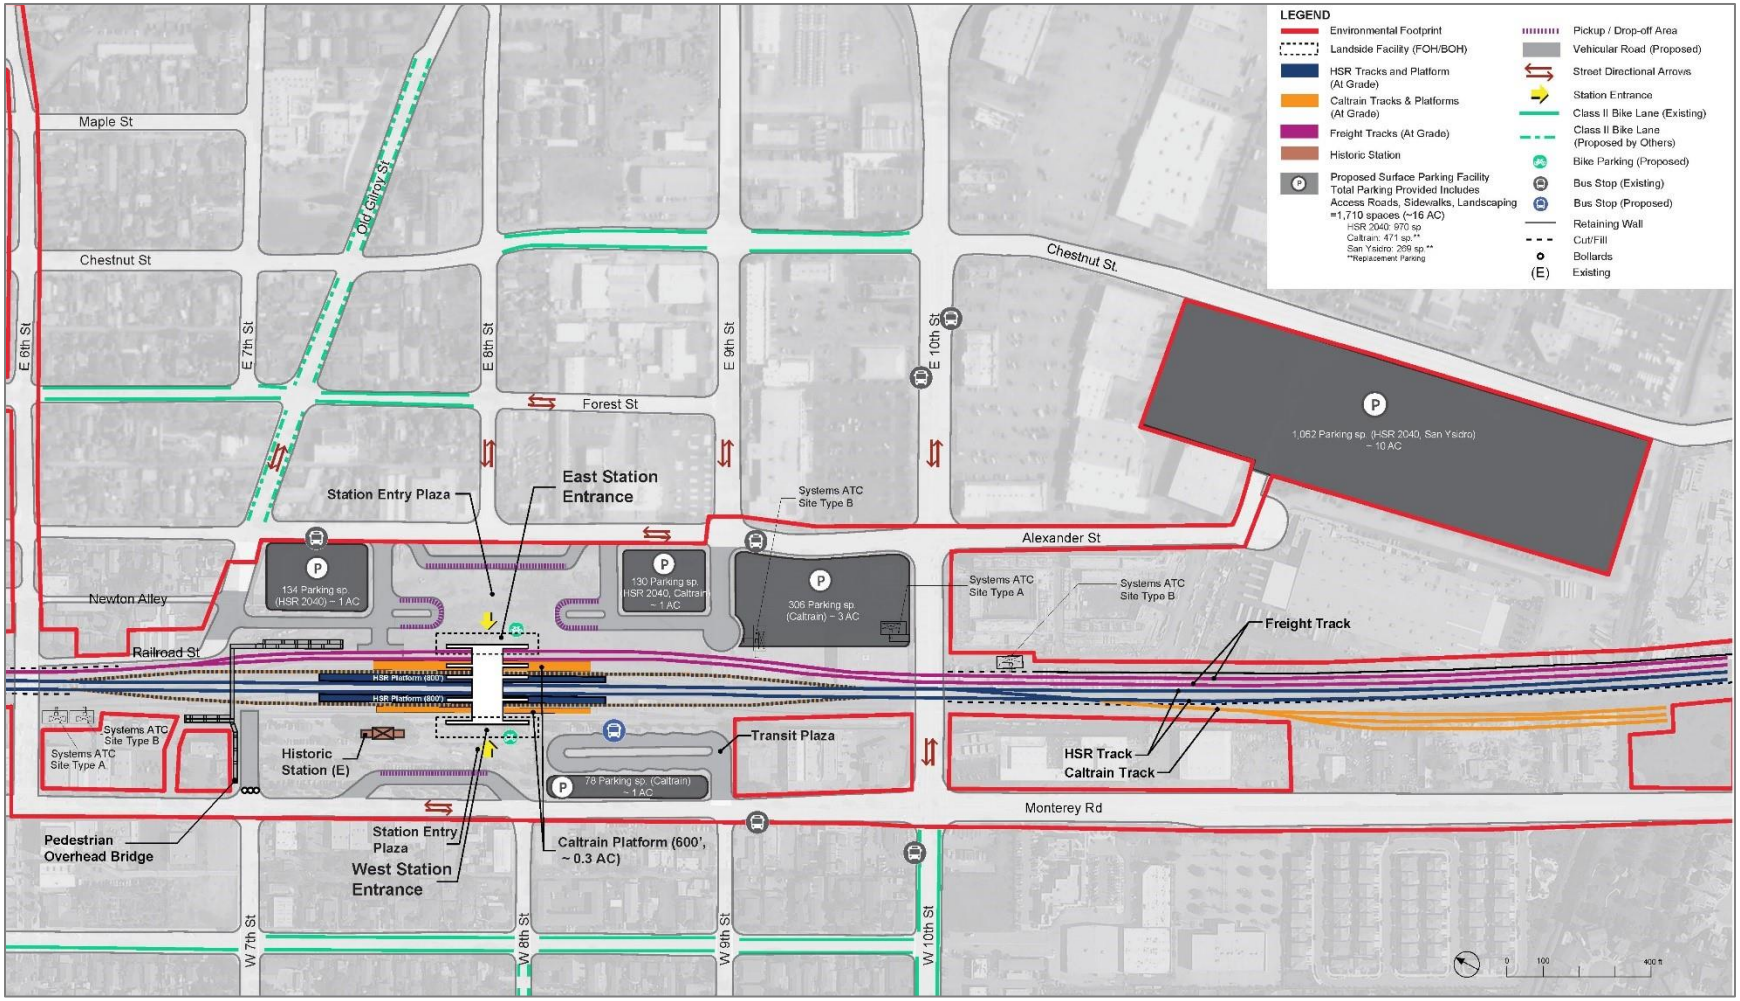
The existing 489 Caltrain parking spaces on the west side of the station would be replaced 1:1 in parking lots on the east and west sides of the alignment. The existing 269 parking spaces at the San Ysidro housing development would be replaced 1:1 with new surface parking at the south end of Alexander Street. HSR parking demand would be 970 spaces in 2040, for a total of 1,728 aggregated parking spaces in 2040. The station site plan provides 970 new parking spaces in five areas. One site would be west of the station along Monterey Road at 9th Street. The other four would be on the east side of the station along Alexander Avenue at 7th Street, 9th Street, 10th Street, and Banes Lane. A multimodal access plan would be developed prior to design and construction of the station. The plan would be developed in coordination with local agencies and would include a parking strategy that would specify the location, amount, and phasing of parking.

A total of eight bus bays would be provided, adding one bay to the existing seven. East 7th Street would be closed and East 10th Street would be modified with quadrant gates and channelization. A pedestrian overcrossing would be installed to provide access between East and West 7th Street. A 4,000-square-foot bicycle facility would be constructed. Figure 2-20 illustrates the conceptual at-grade Downtown Gilroy Station.

The Morgan Hill Caltrain Station would be reconstructed with two new side platforms built outside MT2 and MT3. The platform would be reached by a new pedestrian underpass built at the north end of the platform. The San Martin Caltrain Station would be reconstructed where the existing platform would be removed and a new center platform would be built between MT2 and MT3. The platform would be reached by a new pedestrian overpass constructed at the south end of the platform.

Traction Power Facilities

One new TPSS, Site 4—Gilroy, would be constructed at one of two locations on the east side of the alignment: south of Buena Vista Avenue or north of Cohansey Avenue. At this site, one new utility switching station could be co-located with the TPSS. Communication facilities (i.e., redundant [two underground or one underground and one overhead on existing power structures] fiber optic lines) would also be required to support the electrical interconnections of the TPSS to a new PG&E switching station and/or to existing PG&E facilities, typically within tie-line/utility corridors.



Source: Authority 2019b

JUNE 2019

Figure 2-20 Conceptual Downtown Gilroy At-Grade Station Plan

A traction power switching station would be constructed west of the HSR alignment at Richmond Avenue.

Three traction power paralleling stations would be constructed adjacent to the guideway:

- Either south of San Pedro Avenue on the west side of the alignment or just north of Butterfield Boulevard on the east side of the alignment
- West of Lovers Lane either south of the alignment or north of the alignment (like Alternative 1)
- Near the Tunnel 1 east portal, either at the portal or east of SR 152 in the southern area of Casa de Fruta (like Alternatives 1 and 2)

PG&E would reinforce the electric power distribution network to meet HSR traction and distribution power requirements by replacing (reconductoring) approximately 11.1 miles of existing power line associated with the Spring to Llagas and Green Valley to Llagas 115-kV power lines. The existing power lines to be reconductored, reusing the poles and towers, begin at the Morgan Hill Substation on West Main Avenue in Morgan Hill, then cross the east side of Peak Avenue and Dewitt Avenue, spanning West Dunne Avenue, Chargin Drive, Spring Avenue, and several residences. The alignment would continue south across an open-space area, then follow Sunnyside Avenue for approximately 0.5 mile. The alignment would continue south for approximately 4 miles, spanning additional open-space areas of wineries and the Corde Valley Golf Course. The alignment would then turn east along the north side of Day Road before heading south for approximately 2.5 miles and terminating at the Llagas Substation in Gilroy.

A permanent overhead distribution electrical power line from TPSS Site 4 to the Tunnel 1 portal location would provide power to the tunnel boring machine during construction and the tunnel fire-life-safety system during operations.

Train Control and Communication Facilities

Twenty-two ATC sites would be constructed:

- One site south of Blanchard Road on the east side of the alignment (two site options)
- Three sites south of Live Oak Avenue on the west side of the alignment
- One site north of San Pedro Avenue on the west side of the alignment
- One site north of Barrett Avenue on the west side of the alignment (two site options)
- One site north of East Middle Avenue on the west side of the alignment
- One site in the vicinity of either Church Avenue or Lena Avenue on the east side of the alignment (two site options)
- One site between Leavesley Road and IOOF Avenue
- Two sites south north of Lewis Street on the east side of the alignment
- Two sites south of 6th Street on the west side of the alignment
- Three sites in the vicinity of 10th Street on the east side of the alignment
- Four sites north of Carnadero Avenue on the west side of the alignment
- Two sites east of the Pajaro River
- One site near Lake Road (two site options) (like Alternative 1)

PTC sites would be constructed at the following locations:

- One site south of Blanchard Road
- One site north of Bailey Avenue
- One site co-located with ATC site south of Live Oak Avenue

- One site at Cohansey Avenue
- One site south of Lewis Street
- One site south of East 6th Street

Five stand-alone communications radio sites would be constructed:

- Near Bernal Way on the west side of the alignment (two site options)
- South of Live Oak Avenue on the west side of the alignment (two site options)
- In the vicinity of East Central Avenue (two site options, one on either side of the alignment)
- South of California Avenue on the east side of the alignment
- East of the Pajaro River south of Gilroy

Maintenance Facilities

The South Gilroy MOWF (Figure 2-21) near Bloomfield Road would encompass approximately 50 acres and the program and layout would be as described for Alternatives 1 and 2. In contrast to Alternatives 1 and 2, the MOWF for Alternative 4 would be located on the west side of the tracks between Carnadero Avenue and the Pajaro River. This configuration would require realignment of the UPRR Hollister Subdivision. HSR mainline and MOWF lead track would pass over UPRR Coast Subdivision tracks.

2.2.4.4 Pacheco Pass Subsection

Alignment and Ancillary Features

Alternative 4 would be as described for Alternatives 1–3 for this subsection.

Wildlife Crossings

The wildlife crossings under Alternative 4 would be as described for Alternatives 1–3.

Stations

No new HSR stations are proposed for this subsection.

Traction Power Facilities

Traction power facilities of Alternative 4 would be as described for Alternatives 1–3.

Train Control and Communication Facilities

Train control and communications facilities would be as described for Alternatives 1–3.

Maintenance Facilities

An MOWS would be built near Turner Island Road near Carlucci Road as described for Alternatives 1–3 (Figure 2-13).

2.2.4.5 San Joaquin Valley Subsection

Alignment and Ancillary Features

Alternative 4 would be the same as described for Alternatives 1–3 for this subsection.

Wildlife Crossings

The wildlife crossings under Alternative 4 would be as described for Alternatives 1–3.

Stations

No new HSR stations are proposed for this subsection.

Traction Power Facilities

Traction power facilities would be as described for Alternatives 1–3.

Train Control and Communication Facilities

Train control and communications facilities would be as described for Alternatives 1–3.

Maintenance Facilities

An MOWS would be built near Turner Island Road near Carlucci Road as described for Alternatives 1–3 (Figure 2-13).

2.3 Impact Avoidance and Minimization Features

The Authority has developed impact avoidance and minimization features (IAMF) that would avoid or minimize potential effects. IAMFs are standard practices, actions, and design features that are incorporated into the project to avoid or minimize environmental or community effects. The description of each IAMF details the means and effectiveness of the feature in avoiding or minimizing effects, as well as the environmental benefits of implementing the measure. Table 2-2 shows complete descriptions of all IAMFs that the Authority and FRA would implement to address potential effects related to air quality and GHGs.

Table 2-2 Summary of Air Quality and Greenhouse Gas Impact Avoidance and Minimization Features

IAMF	Description
AQ-IAMF#1: Fugitive Dust Emissions	This action reduces construction-related air quality emissions by requiring the preparation of a fugitive dust control plan. This plan identifies the minimum features that would be implemented during ground-disturbing activities. Examples of these include covering all materials (truck beds) transported on public roads, watering exposed graded surfaces, limiting vehicle speed on the construction site, suspending operations during high wind events, stabilizing all disturbed graded areas, wetting exterior surfaces of structures during demolition, and removing any accumulation of mud or dirt from adjacent public streets. These types of construction best management practices are proven methods of minimizing fugitive dust generation associated with ground-disturbing and demolition construction activities. Each air district traversed by the HSR has adopted rules and/or regulations requiring dust control plans for construction activities. These dust control plans are a part of each district's overall strategy for compliance with federal and state air quality standards.
AQ-IAMF#2: Selection of Coatings	This commitment reduces overall construction emissions by limiting the type of paint to those containing VOC of less than 10 percent (low) to be used during construction. Using paint that releases fewer organic compounds into the air after application is an air quality management measure effective in reducing construction emissions and achieving federal and state air quality standards.

IAMF	Description
AQ-IAMF#3: Renewable Diesel	This commitment requires the contractor to use renewable diesel fuel to minimize and control exhaust emissions from all heavy-duty off-road diesel-fueled construction diesel equipment and on-road diesel trucks. Renewable diesel must meet the most recent ASTM D975 specification for Ultra Low Sulfur Diesel and have a carbon intensity no greater than 50 percent of diesel with the lowest carbon intensity among petroleum diesel fuels sold in California. Using renewable diesel releases less carbon dioxide into the atmosphere, thereby helping reduce greenhouse gas emissions.
AQ-IAMF#4: Reduce Criteria Exhaust Emissions from Construction Equipment	This commitment would be effective in reducing criteria pollutant emissions from off-road equipment. This construction contract requirement would involve utilizing equipment that meets USEPA Tier 4 emission standards, instead of a mix of equipment meeting various engine tiers.
AQ-IAMF#5: Reduce Criteria Exhaust Emissions from On-Road Construction Equipment	This commitment would be effective in reducing criteria pollutant emissions from on-road equipment. This construction contract requirement would involve utilizing model year 2010 or newer on-road engines, instead of a mix of vehicles with various engine model years.
AQ-IAMF#6: Reduce the Potential Impact of Concrete Batch Plants	This measure requires documentation of concrete batch plant location and design requirements. Concrete batch plants would be sited at least 1,000 feet from sensitive receptors. Batch plant technology would include typical control measures to reduce fugitive dust in a manner equivalent to the USEPA AP-42 controlled emissions factors for concrete batch plants. Proper location and utilization of typical control measures would be effective in reducing fugitive dust and health risk during concrete batching.

Source: Authority and FRA 2019
HSR = high-speed rail
VOC = volatile organic compound
USEPA = U.S. Environmental Protection Agency

3 LAWS, REGULATIONS, AND ORDERS

This chapter provides a summary of federal, state, and local laws, regulations, and orders that regulate air quality and GHG and that apply to the project.

Air pollution is a general term that refers to one or more chemical substances that degrade the quality of the atmosphere. Air pollutants degrade the atmosphere by reducing visibility, damaging property, and combining to form smog. Air pollutants result in effects on humans by reducing the productivity or vigor of crops or natural vegetation, and by reducing human or animal health. *Air quality* describes the amount of air pollution to which the public is exposed.

The USEPA is responsible for establishing the national ambient air quality standards (NAAQS), enforcing the CAA (42 United States Code [U.S.C.] § 7401), and regulating transportation-related emission sources, such as aircraft, ships, and certain types of locomotives, under the exclusive authority of the federal government. The USEPA also establishes vehicular emission standards, including those for vehicles sold in states other than California. Automobiles sold in California must meet stricter emission standards established by the California Air Resources Board (CARB).

3.1 Federal

3.1.1 Clean Air Act (42 U.S.C. § 7401) and National Ambient Air Quality Standards

The CAA defines nonattainment areas as geographic regions designated as not meeting one or more of the NAAQS, which are standards that the USEPA has established for six major air pollutants, known as criteria pollutants. It requires that a state implementation plan (SIP) be prepared for each nonattainment area and a maintenance plan be prepared for each former nonattainment area that subsequently demonstrates compliance with the standards. A SIP is a compilation of a state's air quality control plans and rules, approved by the USEPA. Section 176(c) of the CAA provides that federal agencies cannot engage, support, or provide financial assistance for licensing, permitting, or approving any project unless the project conforms to the applicable SIP. The state's and USEPA's goals are to eliminate or reduce the severity and number of violations of the NAAQS and to achieve expeditious attainment of these standards.

The six major criteria pollutants subject to the NAAQS are ozone (O_3), particulate matter (PM) (PM_{10} is PM 10 microns in diameter or less, and $PM_{2.5}$ is PM 2.5 microns in diameter or less), CO, nitrogen dioxide (NO_2), SO_2, and lead (Pb) (Table 3-1). The California ambient air quality standards (CAAQS) are statewide standards established by the CARB that are generally more stringent than the NAAQS and incorporate additional standards for sulfates, hydrogen sulfide, vinyl chloride, and visibility-reducing particles. California's regulations are discussed in more detail in Section 3.2, State.

Table 3-1 summarizes state and federal standards by pollutant. Chapter 4 also shows the standards for each pollutant by averaging time and the method of measurement. The primary standards are intended to protect public health. The secondary standards are intended to protect the nation's welfare and account for air pollutant effects on soil, water, visibility, materials, vegetation, and other aspects of the general welfare.

Table 3-1 State and Federal Ambient Air Quality Standards

Pollutant	Averaging Time	California Standards [1]		National Standards [2]		
		Concentration [3]	Method [4]	Primary [3,5]	Secondary [3, 6]	Method [7]
Ozone (O_3)[8]	1 Hour	0.09 ppm (180 µg/m^3)	Ultraviolet Photometry	—	Same as Primary Standard	Ultraviolet Photometry
	8 Hour	0.070 ppm (137 µg/m^3)		0.070 ppm (137 µg/m^3)		
Respirable Particulate Matter (PM_{10})[9]	24 Hour	50 µg/m^3	Gravimetric or Beta Attenuation	150 µg/m^3	Same as Primary Standard	Inertial Separation and Gravimetric Analysis
	Annual Arithmetic Mean	20 µg/m^3		—		
Fine Particulate Matter ($PM_{2.5}$)[9]	24 Hour	—	—	35 µg/m^3	Same as Primary Standard	Inertial Separation and Gravimetric Analysis
	Annual Arithmetic Mean	12 µg/m^3	Gravimetric or Beta Attenuation	12.0 µg/m^3	15 µg/m^3	
Carbon Monoxide (CO)	1 Hour	20 ppm (23 mg/m^3)	Non-Dispersive Infrared Photometry	35 ppm (40 mg/m^3)	—	Non-Dispersive Infrared Photometry
	8 Hour	9.0 ppm (10 mg/m^3)		9 ppm (10 mg/m^3)	—	
	8 Hour (Lake Tahoe)	6 ppm (7 mg/m^3)		—	—	
Nitrogen Dioxide (NO_2)[10]	1 Hour	0.18 ppm (339 µg/m^3)	Gas Phase Chemiluminescence	100 ppb (188 µg/m^3)	—	Gas Phase Chemiluminescence
	Annual Arithmetic Mean	0.030 ppm (57 µg/m^3)		0.053 ppm (100 µg/m^3)	Same as Primary Standard	
Sulfur Dioxide (SO_2)[11]	1 Hour	0.25 ppm (655 µg/m^3)	Ultraviolet Fluorescence	75 ppb (196 µg/m^3)	—	Ultraviolet Fluorescence; Spectrophotometry (Pararosaniline Method)
	3 Hour	—		—	0.5 ppm (1300 µg/m^3)	
	24 Hour	0.04 ppm (105 µg/m3)		0.14 ppm (for certain areas)[11]	—

Source: CARB 2016
°C = degrees Celsius
CAAQS = California ambient air quality standards
CARB = California Air Resources Board
CO = carbon monoxide
NAAQS = national ambient air quality standards
mg/m^3 = milligrams per cubic meter
NO_2 = nitrogen dioxide
O_3 = ozone
Pb = lead
$PM_{2.5}$ = particulate matter 2.5 microns or less in diameter
PM_{10} = particulate matter 10 microns or less in diameter
ppb = parts per billion
ppm = parts per million
SO_2 = sulfur dioxide
TAC = toxic air contaminants
USEPA = U.S. Environmental Protection Agency
> = greater than
N/A = not applicable or there was insufficient or no data available to determine the value
µg/m^3 = micrograms per cubic meter of air
— = no standard

[1] California standards for O_3, CO (except 8-hour Lake Tahoe), SO_2 (1 and 24 hour), NO_2, and particulate matter (PM_{10}, $PM_{2.5}$, and visibility-reducing particles) are values that are not to be exceeded. All others are not to be equaled or exceeded. CAAQS are listed in the Table of Standards in Section 70200 of Title 17 of the California Code of Regulations

[2] National standards (other than O_3, PM, and those based on annual arithmetic mean) are not to be exceeded more than once per year. The O_3 standard is attained when the fourth highest 8-hour concentration measured at each site in a year, averaged over 3 years, is equal to or less than the standard. For PM_{10}, the 24-hour standard is attained when the expected number of days per calendar year with a 24-hour average concentration above 150 µg/m^3 is equal to or less than 1. For $PM_{2.5}$, the 24-hour standard is attained when 98 percent of the daily concentrations, averaged over 3 years, are equal to or less than the standard. Contact the USEPA for further clarification and current national policies.

[3] Concentration expressed first in units in which it was promulgated. Equivalent units given in parentheses are based upon a reference temperature of 25°C and a reference pressure of 760 torr. Most measurements of air quality are to be corrected to a reference temperature of 25°C and a reference pressure of 760 torr; ppm in this table refers to ppm by volume, or micromoles of pollutant per mole of gas.

[4] Any equivalent measurement method which can be shown to the satisfaction of the CARB to give equivalent results at or near the level of the air quality standard may be used.
[5] National Primary Standards: The levels of air quality necessary, with an adequate margin of safety to protect the public health.
[6] National Secondary Standards: The levels of air quality necessary to protect the public welfare from any known or anticipated effects of a pollutant.
[7] Reference method as described by the USEPA. An "equivalent method" of measurement may be used but must have a "consistent relationship to the reference method" and must be approved by the USEPA.
[8] On October 1, 2015, the national 8-hour O_3 primary and secondary standards were lowered from 0.075 to 0.070 ppm.
[9] On December 14, 2012, the national annual $PM_{2.5}$ primary standard was lowered from 15 µg/m^3 to 12.0 µg/m^3. The existing national 24-hour $PM_{2.5}$ standards (primary and secondary) were retained at 35 µg/m^3, as was the annual secondary standard of 15 µg/m^3. The existing 24-hour PM_{10} standards (primary and secondary) of 150 µg/m^3 also were retained. The form of the annual primary and secondary standards is the annual mean, averaged over 3 years.
[10] To attain the 1-hour national standard, the 3-year average of the annual 98th percentile of the 1-hour daily maximum concentrations at each site must not exceed 100 ppb. Note that the national 1-hour standard is in units of ppb. California standards are in units of ppm. To directly compare the national 1-hour standard to the California standards, the units can be converted from ppb to ppm. In this case, the national standard of 100 ppb is identical to 0.100 ppm.
[11] On June 2, 2010, a new 1-hour SO_2 standard was established and the existing 24-hour and annual primary standards were revoked. To attain the 1-hour national standard, the 3-year average of the annual 99th percentile of the 1-hour daily maximum concentrations at each site must not exceed 75 ppb. The 1971 SO_2 national standards (24-hour and annual) remain in effect until 1 year after an area is designated for the 2010 standard, except that in areas designated nonattainment for the 1971 standards, the 1971 standards remain in effect until implementation plans to attain or maintain the 2010 standards are approved. Note that the 1-hour national standard is in units of ppb. California standards are in units of ppm. To directly compare the 1-hour national standard to the California standard, the units can be converted to ppm. In this case, the national standard of 75 ppb is identical to 0.075 ppm.
[12] The CARB has identified Pb and vinyl chloride as TAC with no threshold level of exposure for adverse health effects determined. These actions allow for the implementation of control measures at levels below the ambient concentrations specified for these pollutants.
[13] The national standard for Pb was revised on October 15, 2008, to a rolling 3-month average. The 1978 Pb standard (1.5 µg/m^3 as a quarterly average) remains in effect until 1 year after an area is designated for the 2008 standard, except that in areas designated nonattainment for the 1978 standard, the 1978 standard remains in effect until implementation plans to attain or maintain the 2008 standard are approved.
[14] In 1989, the CARB converted both the general statewide 10-mile visibility standard and the Lake Tahoe 30-mile visibility standard to instrumental equivalents, which are "extinction of 0.23 per kilometer" and "extinction of 0.07 per kilometer" for the statewide and Lake Tahoe Air Basin standards, respectively.

3.1.2 Conformity Rule

Pursuant to CAA Section 176(c) requirements, the USEPA promulgated 40 C.F.R. Part 51, Subpart W and 40 C.F.R. Part 93B, Determining Conformity of General Federal Actions to State or Federal Implementation Plans (§ 63214) (November 30, 1993) as amended; 75 *Federal Register* (Fed. Reg.) 17253 (April 5, 2010). These regulations, commonly referred to as the General Conformity Rule, apply to all federal actions, including FRA actions on the HSR System. Federal actions that are excluded from review (e.g., stationary emission sources that hold permits under the federal New Source Review program) or related to transportation plans, programs, and projects under the Federal Highway Act (Title 23 U.S.C.) or the Federal Transit Act (Title 49 U.S.C.) are not subject to General Conformity. Transportation actions under Title 23 or Title 49 are subject to transportation conformity (40 C.F.R. Part 51T and 40 C.F.R. Part 93A). 40 C.F.R. Part 51, Subpart W, applies in states that have an approved SIP revision adopting the General Conformity Rule.

The General Conformity Rule is used to determine if federal actions meet the requirements of the CAA and the applicable SIP so that air emissions related to the action do not result in the following outcomes:

- Cause or contribute to new violations of an NAAQS
- Increase the frequency or severity of any existing violation of an NAAQS
- Delay timely attainment of an NAAQS or interim emission reduction

A conformity determination under the General Conformity Rule is required if the federal agency determines that all of the following criteria apply:

- The action will occur in a nonattainment or maintenance area
- One or more specific exemptions do not apply to the action
- The action is not included in the federal agency's "presumed to conform" list
- The emissions from the proposed action are not within the approved emissions budget for an applicable facility
- The total direct and indirect emissions of a pollutant (or its precursors) are at or above the *de minimis* levels established in the General Conformity Rule (75 Fed. Reg. 17255)

Conformity regulatory criteria are listed in 40 C.F.R. Section 93.158. An action would be determined to conform to the applicable SIP if, for each pollutant that exceeds the *de minimis* emissions level in 40 C.F.R. Section 93.153(b), or otherwise requires a conformity determination because of the total of direct and indirect emissions from the action, the action meets the requirements of 40 C.F.R. Section 93.158(c).

In addition, federal activities may not cause or contribute to new violations of air quality standards, exacerbate existing violations, or interfere with timely attainment or required interim emissions reductions toward attainment. The project is subject to review under the USEPA General Conformity Rule.

3.1.3 Mobile Source Air Toxics/Hazardous Air Pollutants

In addition to the NAAQS criteria pollutants, the USEPA regulates MSATs. MSATs are compounds emitted from highway vehicles and nonroad equipment that are known or suspected to cause cancer or other serious health and environmental effects. In February 2007, the USEPA finalized a rule (Control of Hazardous Air Pollutants from Mobile Sources, February 9, 2007) to reduce hazardous air pollutants (HAP) from mobile sources. The rule limits the benzene content of gasoline and reduces toxic emissions from passenger vehicles and gas cans. The USEPA estimates that in 2030 this rule would reduce total emissions of MSATs by 330,000 tons and volatile organic compound (VOC) emissions (precursors to O_3 and $PM_{2.5}$) by more than 1 million tons. The latest revision to this rule, which added specific benzene control technologies, occurred

in October 2008. No NAAQS or CAAQS exist for MSATs. Specifically, the USEPA has not established NAAQS or provided ambient standards for HAPs.

On October 18, 2016, the FHWA released *Updated Interim Guidance on Mobile Source Air Toxic Analysis in NEPA Documents,* which superseded the February 2006 interim guidelines. The FHWA's guidance advises when and how to analyze MSATs in the NEPA environmental review process for highways and other transportation-related projects. This guidance was followed to define the MSAT analysis for the project.

By 2010, the USEPA's existing programs had reduced MSATs by more than 1 million tons from 1999 levels (USEPA 2015a). In addition to controlling pollutants such as hydrocarbons, PM, and nitrogen oxides (NO_X), recent USEPA regulations controlling emissions from highway vehicles and nonroad equipment will result in large reductions in toxic emissions to the air. The USEPA is developing programs that would provide additional benefits (further controls) for small non-road gasoline engines, diesel locomotives, and marine engines. Several USEPA programs reduce risk in communities. These programs include Clean School Bus USA, the Voluntary Diesel Retrofit Program, Best Workplaces for Commuters, and the National Clean Diesel Campaign.

3.1.4 Federal Greenhouse Gas Regulations and Guidance

Climate change and GHG emission reductions are a concern at the federal level. Laws, regulations, plans, and policies address global climate change issues. This section summarizes key federal regulations relevant to the proposed project.

In *Massachusetts v. U.S. Environmental Protection Agency, et al.*, 549 U.S. 497 (2007), the United States Supreme Court ruled that GHGs fit within the CAA's definition of air pollutants and that the USEPA has the authority to regulate GHGs.

On September 22, 2009, the USEPA published the Final Rule that requires mandatory reporting of GHG emissions from large sources in the U.S. The rule amends CAA Regulations under 40 C.F.R. Parts 86, 87, 89, 90, and 94 and provides a new section, Part 98. The USEPA uses the reports to collect accurate and comprehensive emissions data that can inform future policy decisions. Facilities that emit 25,000 metric tons or more per year of GHG emissions must submit annual reports to the USEPA under Subpart C of the final rule. The final rule covers the GHGs carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), hydrofluorocarbons, perfluorocarbons, sulfur hexafluoride (SF_6), and other fluorinated gases, including nitrogen trifluoride and hydrofluorinated ethers. This is not a transportation-related regulation. However, the methodology developed as part of this regulation is helpful in identifying potential GHG emissions.

On October 5, 2009, President Obama signed U.S. Presidential Executive Order (USEO) 13514; *Federal Leadership in Environmental, Energy, and Economic Performance*. USEO 13514 requires federal agencies to set a 2020 GHG emission-reduction target within 90 days, increase energy efficiency, reduce fleet petroleum consumption, conserve water, reduce waste, support sustainable communities, and leverage federal purchasing power to promote environmentally responsible products and technologies. On December 7, 2009, the *Final Endangerment and Cause or Contribute Findings for Greenhouse Gases* under Section 202(a) of the CAA went into effect. The endangerment finding states that current and projected concentrations of the six key well-mixed GHGs in the atmosphere—CO_2, CH_4, N_2O, hydrofluorocarbons, perfluorocarbons, and SF_6—threaten the public health and welfare of current and future generations. Furthermore, it states that the combined emissions of these well-mixed GHGs from new motor vehicles and new motor vehicle engines contribute to the GHG pollution that threatens public health and welfare (USEPA 2015b).

Based on the endangerment finding, the USEPA revised vehicle emission standards under the CAA. The USEPA and the NHTSA issued a joint final rulemaking to update the Corporate Average Fuel Economy (CAFE) fuel standards on October 15, 2012 (77 Fed. Reg. 62623), requiring substantial improvements in fuel economy and reductions in GHG emissions for all light-duty vehicles sold in the U.S. The new standards apply to new passenger cars, light-duty trucks, and medium-duty passenger vehicles, covering model years 2017–2025. The USEPA GHG standards require that these vehicles meet an estimated combined average emissions level of

163 grams of CO_2 per mile in model year 2025, which would be equivalent to 54.5 miles per gallon if the automotive industry were to meet this CO_2 level entirely through fuel economy improvements.

On September 15, 2011, the USEPA and NHTSA issued a final rule of *Greenhouse Gas Emissions Standards and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles* (76 Fed. Reg. 7106). This final rule is tailored to each of three regulatory categories of heavy-duty vehicles—combination tractors, heavy-duty pickup trucks and vans, and vocational vehicles—and applies to model years 2014–2018. The USEPA and NHTSA estimated that the new standards in this rule will reduce CO_2 emissions by approximately 270 million metric tons (MT) and save 530 million barrels of oil over the life of vehicles sold during the 2014–2018 model years. The USEPA and NHTSA signed Phase 2 of these standards on August 16, 2016, which apply to model years 2019–2027 medium- and heavy-duty vehicles. The USEPA and NHTSA have determined that the Phase 2 standards would lower CO_2 emissions by approximately 1.1 billion metric tons and save up to 2 billion barrels of oil over the life of vehicles regulated under the program (USEPA 2016a).

On October 15, 2012, the USEPA and the NHTSA issued CAFE standards for model years 2017 and beyond; these standards will reduce GHG emissions by increasing the fuel economy of light-duty vehicles to 54.5 miles per gallon by model year 2025. To further California's support of the national program to regulate emissions, the CARB submitted a proposal that would allow automobile manufacturer compliance with the USEPA's requirements to show compliance with California's requirements for the same model years. The Final Rulemaking Package was filed on December 6, 2012, and the final rulemaking became effective December 31, 2012. In July 2016, the USEPA, NHTSA, and CARB released a mid-term evaluation of the October 2012 final rule in a draft technical assessment report (USEPA et al. 2016). The draft technical assessment report makes the following conclusions:

- A wider range of technologies exists for manufacturers to meet the model year 2022–2025 standards, and at costs that are similar or lower, than those projected in the 2012 rule.
- Advanced gasoline vehicle technologies will continue to be the predominant technologies, with modest levels of strong hybridization and very low levels of full electrification (plug-in vehicles) needed to meet the standards.
- The car/truck mix reflects updated consumer trends that are informed by a range of factors including economic growth, gasoline prices, and other macro-economic trends. However, as the standards were designed to yield improvements across the light-duty vehicle fleet, irrespective of consumer choice, updated trends are fully accommodated by the footprint-based standards.

On August 2, 2018, NHTSA and USEPA proposed to amend the fuel efficiency standards for passenger cars and light trucks and establish new standards covering model years 2021 through 2026 by maintaining the current model year 2020 standards through 2026 (SAFE Vehicles Rule). On September 19, 2019, USEPA and NHTSA issued a final action on the One National Program Rule, which is consider Part One of the SAFE Vehicles Rule and a precursor to the proposed fuel efficiency standards. Part One of the SAFE Vehicles Rule enables USEPA/NHTSA to provide nationwide uniform fuel economy and GHG vehicle standards, specifically by (1) clarifying that federal law preempts state and local tailpipe GHG standards, (2) affirming NHTSA's statutory authority to set nationally applicable fuel economy standards, and (3) withdrawing California's CAA preemption waiver to set state-specific standards.

USEPA and NHTSA published their decisions to withdraw California's waiver and finalize regulatory text related to the preemption on September 27, 2019 (84 Fed. Reg. 51310). California, 22 other states, the District of Columbia, and two cities filed suit against Part One of the SAFE Vehicles Rule on September 20, 2019 (*California et al. v. United States Department of Transportation et al*., 1:19-cv-02826, U.S. District Court for the District of Columbia). On October 28, 2019, the Union of Concerned Scientists, Environmental Defense Fund, and other groups filed a protective petition for review after the federal government sought to transfer the suit to the

D.C. Circuit (*Union of Concerned Scientists v. National Highway Traffic Safety Administration*). The lawsuit filed by California and others is stayed pending resolution of the petition.

USEPA and NTHSA published final rules to amend and establish national CO_2 and fuel economy standards on April 30, 2020 (Part Two of the SAFE Vehicles Rule) (85 Fed. Reg. 24174). The revised rule changes the national fuel economy standards for light-duty vehicles from 50.4 miles per gallon to 40.5 miles per gallon in future years. California, 22 other states, and the District of Columbia filed a petition for review of the final rule on May 27, 2020.

On January 20, 2021, President Joseph Biden issued an executive order directing the USEPA and NHTSA to review the SAFE Vehicles Rule and propose a new rule suspending, revising, or rescinding it. On April 22, 2021, NTHSA issued a notice of proposed rulemaking to repeal the SAFE Vehicles Rule (49 C.F.R. Parts 531 and 533). The fate of the SAFE Vehicles Rule remains uncertain in the face of pending legal deliberations.

On February 18, 2010, the White House Council on Environmental Quality (CEQ) released draft guidance regarding the consideration of GHG in NEPA documents for federal actions. The CEQ issued revised draft guidance in December 2014 and final guidance in August 2016 (CEQ 2016). On April 25, 2017, CEQ withdrew the guidance pursuant to USEO 13783, but noted "the withdrawal of the guidance does not change any law, regulation, or other legally binding requirement (82 Fed. Reg. 16576)." The CEQ released new draft guidance on June 26, 2019, which if finalized would replace the withdrawn August 2016 guidance. The June 2019 guidance requires federal agencies to analyze the direct, indirect, and cumulative impacts of a proposed action's GHG emissions, as well as consider the impacts of climate change on the project.

3.2 State

3.2.1 California Clean Air Act and California Ambient Air Quality Standards

The California Clean Air Act requires that nonattainment areas achieve and maintain the health-based CAAQS by the earliest practicable date. The act is administered by the CARB at the state level and by local air quality management districts at the regional level. The air districts are required to develop plans and control programs for attaining the state standards.

The CARB is responsible for implementation of the California Clean Air Act, meeting state requirements of the federal CAA, and establishing the CAAQS. The CARB is also responsible for setting emission standards for vehicles sold in California and for other emission sources, such as consumer products and certain off-road equipment. The CARB also establishes passenger vehicle fuel specifications.

3.2.2 Mobile Source Air Toxics/Toxic Air Contaminates

California regulates TACs (equivalent to the federal HAPs) primarily through the Toxic Air Contaminant Identification and Control Act (Tanner Act) and the Air Toxics "Hot Spots" Information and Assessment Act of 1987 (Hot Spots Act). The Tanner Act created California's program to reduce exposure to air toxics. The Hot Spots Act supplements the Tanner Act by requiring a statewide air toxics inventory, notification of people exposed to a significant health risk, and facility plans to reduce these risks.

In August 1998, the CARB identified diesel particulate matter (DPM) from diesel-fueled engines as a TAC. In September 2000, the CARB approved a comprehensive Diesel Risk Reduction Plan to reduce emissions from both new and existing diesel-fueled engines and vehicles. The goal of the plan was to reduce DPM (respirable particulate matter) emissions and the associated health risk by 75 percent in 2010 and by 85 percent by 2020. The plan identifies 14 measures that target new and existing on-road vehicles (e.g., heavy-duty trucks and buses), off-road equipment (e.g., graders, tractors, forklifts, sweepers, and boats), portable equipment (e.g., pumps), and stationary engines (e.g., stand-by power generators).

The CARB has adopted regulations to reduce emissions from both on-road and off-road heavy-duty diesel vehicles (e.g., equipment used in construction). These regulations, known as Airborne

Toxic Control Measures, reduce the idling of school buses and other commercial vehicles, control DPM, and limit the emissions of ocean-going vessels in California waters. The regulations also include measures to control emissions of air toxics from stationary sources. The California Toxics Inventory, developed by interpolating from CARB estimates of total organic gases and PM, provides emissions estimates by stationary, area-wide, on-road mobile, off-road mobile, and natural sources (CARB 2015a).

3.2.3 California Greenhouse Gas Regulations and Guidance

California has taken proactive steps, briefly described in this section, to address the issues associated with GHG emissions and climate change.

3.2.3.1 Assembly Bill 1493

With the passage of Assembly Bill (AB) 1493 in 2002, California launched an innovative and proactive approach to dealing with GHG emissions and climate change at the state level. AB 1493 requires the CARB to develop and implement regulations to reduce automobile and light-truck GHG emissions. These stricter emissions standards were designed to apply to automobiles and light trucks beginning with the model year 2009. Although litigation challenged these regulations and the USEPA initially denied California's related request for a waiver, the waiver request was granted (CARB 2015b).

3.2.3.2 Executive Order S-3-05

On June 1, 2005, Governor Arnold Schwarzenegger signed California Executive Order (EO) S-3-05. The goal of this EO was to reduce California's GHG emissions to (1) 2000 levels by 2010; (2) 1990 levels by 2020; and (3) 80 percent below the 1990 levels by 2050. EO S-3-05 also calls for the California Environmental Protection Agency to prepare biennial science reports on the potential impact of continued global warming on certain sectors of the California economy. As a result of the scientific analysis presented in these biennial reports, a comprehensive Climate Adaptation Strategy was released in December 2009 following extensive interagency coordination and stakeholder input. The latest of these reports, Climate Action Team Biennial Report, was published in December 2010 (Cal-EPA 2010).

3.2.3.3 Assembly Bill 32

One goal of EO S-03-05 was further reinforced by AB 32 (Chapter 488, Statutes of 2006), the Global Warming Solutions Act of 2006, which requires the state to reduce GHG emissions to 1990 levels by 2020. AB 32 mandates that the CARB create a plan that includes market mechanisms and implement rules to achieve "real, quantifiable, cost-effective reductions of GHGs." Separately, Governor Schwarzenegger signed EO S-20-06, which directs state agencies to begin implementing AB 32, including the recommendations made by the State's Climate Action Team.

The following are specific requirements of AB 32:

- The CARB will prepare and approve a scoping plan for achieving the maximum technologically feasible and cost-effective reductions in GHG emissions from sources or categories of sources of GHGs by 2020 (Cal. Health and Safety Code § 38561). The scoping plan, approved by the CARB on December 12, 2008, and updated in 2014 and 2017, provides the outline for future actions to reduce GHG emissions in California via regulations, market mechanisms, and other measures. The scoping plan includes the implementation of the HSR system as a GHG reduction measure, estimating a 2020 reduction of 1 million metric tons (t) of CO_2 equivalent (CO_2e).
- The CARB will identify the statewide level of GHG in 1990 to serve as the emissions limit to be achieved by 2020 (Cal. Health and Safety Code § 38550). In December 2007, the CARB approved the 2020 emission limit of 427 million metric tons of CO_2e of GHG.
- The CARB will adopt a regulation requiring the mandatory reporting of GHG emissions (Cal. Health and Safety Code § 38530). In December 2007, the CARB adopted a regulation requiring the largest industrial sources to report and verify their GHG emissions. The

reporting regulation serves as a solid foundation to determine GHG emissions and track future changes in emission levels.

As of July 2016, California is on track to meet or exceed the target of reducing GHG to 1990 levels by 2020, which was previously established in the California Global Warming Solutions Act of 2006 (AB 32).

3.2.3.4 Executive Order S-01-07

With EO S-01-07, Governor Schwarzenegger set forth the low carbon fuel standard for California in 2007. Under this EO, the carbon intensity of California's transportation fuels is to be reduced by at least 10 percent by 2020.

3.2.3.5 California Environmental Quality Act Guidelines Amendments to Address Greenhouse Gas Emissions

The State CEQA Guidelines amendments of December 30, 2009, specifically require lead agencies to address GHG emissions in determining the significance of environmental effects caused by a project, and to consider feasible means to mitigate the significant effects of GHG emissions. The following provisions of the State CEQA Guidelines amendments pertain to addressing GHG emissions (CNRA 2018):

- A lead agency may consider the following when assessing the significance of effects from GHG emissions:
  - The extent to which the project may increase or reduce GHG emissions as compared to the existing environmental setting
  - Whether the project emissions exceed a threshold of significance that the lead agency determines applies to the project
  - The extent to which the project complies with regulations or requirements adopted to implement a statewide, regional, or local plan for the reduction or mitigation of GHG emissions
- When an agency makes a statement of overriding considerations, the agency may consider adverse environmental effects in the context of region wide or statewide environmental benefits.
- Lead agencies will consider feasible means of mitigating GHG emissions that may include, but not be limited to, the following:
  - Measures in an existing plan or mitigation program for the reduction of emissions that are required as part of the lead agency's decision.
  - Reductions in emissions resulting from a project through implementation of project features, project design, or other measures.
  - Off-site measures, including offsets.
  - Measures that sequester GHGs.
- In the case of the adoption of a plan (e.g., general plan, long-range development plan, or GHG reduction plan), mitigation may include specific measures that may be implemented on a project-by-project basis. Mitigation may also incorporate specific measures or policies found in an adopted ordinance or regulation that reduces the cumulative effect of emissions.

3.2.3.6 Senate Bill 375

SB 375, signed into law by Governor Schwarzenegger on September 30, 2008, became effective January 1, 2009. This law requires the state's 18 metropolitan planning organizations to develop the sustainable communities strategies (SCS) as part of their regional transportation plans (RTP) through integrated land use and transportation planning, and to demonstrate an ability to attain the GHG emissions reduction targets that the CARB established for the region by 2020 and 2035. This would be accomplished through either the financially constrained SCS as part of the RTP or an unconstrained alternative planning strategy. If regions develop integrated land use, housing,

and transportation plans that meet the SB 375 targets, new projects in these regions can be relieved of certain CEQA review requirements.

In accordance with SB 375, the CARB appointed the Regional Targets Advisory Committee on January 23, 2009, to provide recommendations on factors to be considered and methodologies to be used in the CARB's target setting process. The Regional Targets Advisory Committee was required to provide its recommendations in a report to the CARB by September 30, 2009, to include any relevant issues such as data needs, modeling techniques, growth forecasts, jobs-housing balance, interregional travel, various land use/transportation issues affecting GHG emissions, and overall issues relating to setting these targets. The CARB adopted final targets on September 23, 2010. The CARB must update the regional targets every 8 years (or 4 years if it so chooses) consistent with each metropolitan planning organization's update of its RTP. The targets were last revised in March 2018.

3.2.3.7 Executive Order B-30-15

Governor Jerry Brown signed EO B-30-15 on April 29, 2015. EO B-30-15 established a medium-term goal for 2030 of reducing GHG emissions by 40 percent below 1990 levels and requires the CARB to update its current AB 32 Scoping Plan to identify measures to meet the 2030 target. The EO B-30-15 supports EO S-3-05 but is only binding on state agencies.

3.2.3.8 Senate Bill 32 and Assembly Bill 197

Senate Bill (SB) 32 requires the CARB to verify that statewide GHG emissions are reduced to at least 40 percent below the 1990 level by 2030, consistent with the target set forth in EO B-30-15. AB 197 creates requirements to form the Joint Legislative Committee on Climate Change Policies, requires the CARB to prioritize direct emission reductions and consider social costs when adopting regulations to reduce GHG emissions beyond the 2020 statewide limit, requires the CARB to prepare reports on sources of GHGs and other pollutants, establishes 6-year terms for voting members of the CARB, and adds two legislators as nonvoting members of the CARB. Both bills were signed by Governor Brown on September 8, 2016.

3.2.3.9 Senate Bill 100

The state's existing renewables portfolio standard requires all retail sellers to procure a minimum quantity of electricity products from eligible renewable energy resources so that the total kilowatt hours of those products sold to their retail end-use customers achieve 25 percent of retail sales by December 31, 2016 (achieved), 33 percent by December 31, 2020, 40 percent by December 31, 2024, 45 percent by December 31, 2027, and 50 percent by December 31, 2030. SB 100 revises and extends these renewable resource targets to 50 percent by December 31, 2026, 60 percent December 31, 2030, and 100 percent by December 31, 2045.

3.2.3.10 Executive Order B-55-18

EO B-55-18 acknowledges the environmental, community, and public health risks posed by future climate change. It further recognizes the climate stabilization goal adopted by 194 states and the European Union under the Paris Agreement. While the United States was not party to the agreement, California is committed to meeting the Paris Agreement goals and going beyond them wherever possible. Based on the worldwide scientific agreement that carbon neutrality must be achieved by midcentury, EO B-55-18 establishes a new state goal to achieve carbon neutrality as soon as possible, and no later than 2045, and to achieve and maintain net negative emissions thereafter. The EO charges the CARB with developing a framework for implementing and tracking progress towards these goals. This EO extends EO S-3-05, but is only binding on state agencies.

3.2.3.11 Innovative Clean Transit Regulation

The CARB approved the Innovative Clean Transit Regulation on December 14, 2018. The regulation sets a statewide goal for public transit agencies to gradually transition to 100 percent zero-emission bus fleets by 2040. Transiting bus fleets to zero-emissions vehicles is expected to reduce GHG emissions by 19 million metric tons CO_2e between 2020 and 2050 (CARB 2018a).

3.2.4 California Asbestos Control Measures

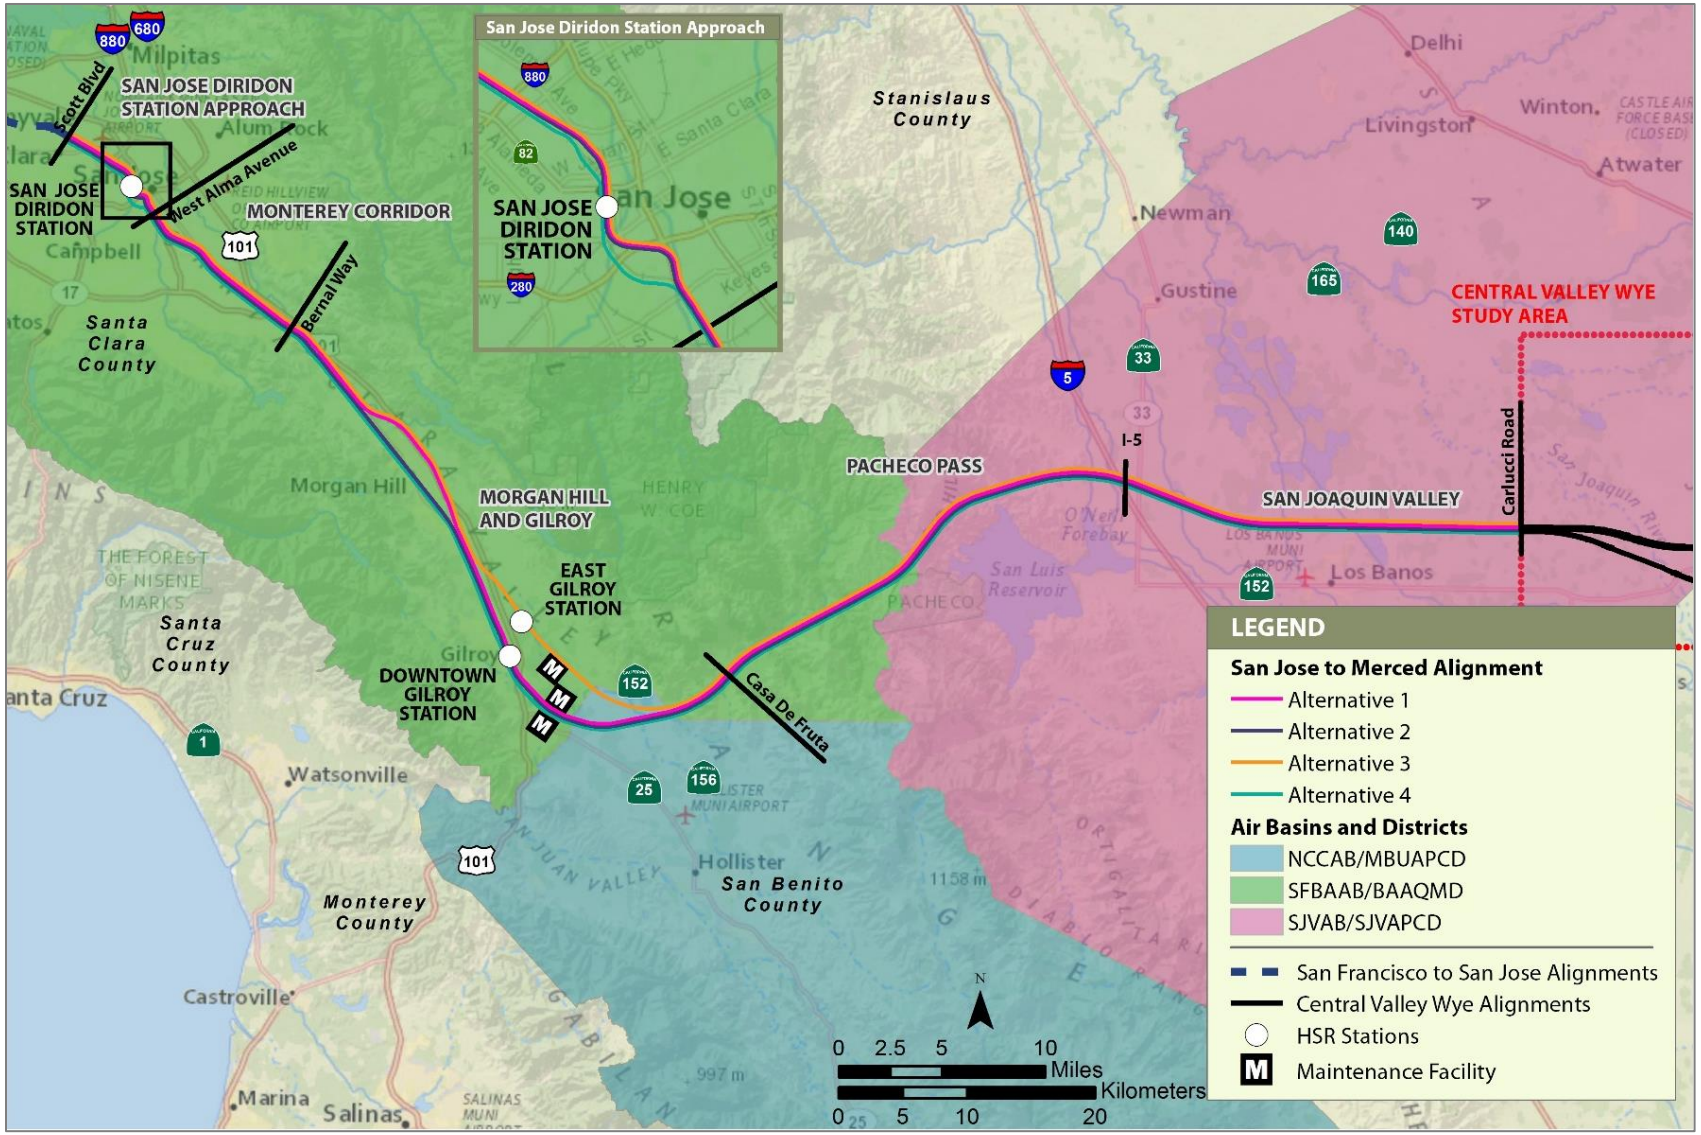
The CARB has adopted two airborne toxic control measures for controlling naturally occurring asbestos (NOA): the *Asbestos Airborne Toxic Control Measure for Surfacing Applications* (BAAQMD 2015) and the *Asbestos Airborne Toxic Control Measure for Construction, Grading, Quarrying, and Surface Mining Operations* (BAAQMD 2002). While the USEPA is responsible for enforcing regulations relating to asbestos renovations and demolitions, it can delegate this authority to state and local agencies. The CARB and local air districts have been delegated authority to enforce the Federal National Emission Standards for HAPs regulations for asbestos.

3.3 Regional and Local

3.3.1 Air Quality Management Districts

The project crosses three air basins—San Francisco Bay Area Air Basin (SFBAAB), North Central Coast Air Basin (NCCAB), and SJVAB—and falls under the jurisdiction of three air districts—BAAQMD, MBARD, and SJVAPCD (see Figure 3-1). The BAAQMD, MBARD, and SJVAPCD are responsible for the following actions:

- Implementing air quality regulations, including developing plans and control measures for stationary sources of air pollution to meet the NAAQS and CAAQS.
- Implementing permit programs for the construction, modification, and operation of sources of air pollution.
- Coordinating with local transportation planning agencies on mobile emissions inventory development, transportation control measure development and implementation, and transportation conformity.
- Enforcing air pollution statutes and regulations governing stationary sources. With CARB oversight, the air districts also administer local regulations.



Source: Authority 2019b; CARB 2012

JANUARY 2020

Figure 3-1 Air Basins and Air Districts in the Resource Study Area

3.3.1.1 Bay Area Air Quality Management District

The BAAQMD has local air quality jurisdiction over projects in the SFBAAB including Santa Clara County. BAAQMD has adopted advisory emission thresholds to assist CEQA lead agencies in determining the level of significance of a project's emissions, which are outlined in its *California Environmental Quality Act Air Quality Guidelines* (CEQA Guidelines) (BAAQMD 2017a). The BAAQMD CEQA Guidelines outline advisory thresholds for stationary source and land use development projects. BAAQMD has also adopted air quality plans to improve air quality, protect public health, and protect the climate.

The project may be subject to the following district rules. This list of rules may not be all-encompassing because additional BAAQMD rules may apply to the project as specific components are identified. There are also local city and county policies that pertain to air quality and climate change. The policies of the general plans focus on managing sources of air pollutants through mixed-use and transit- and pedestrian-friendly neighborhoods.[7]

- **Regulation 2, Rule 2 (New Source Review)**—This rule contains requirements for Best Available Control Technology and emission offsets.
- **Regulation 2, Rule 5 (New Source Review of Toxic Air Contaminates)**—This rule outlines guidance for evaluating TAC emissions and their potential health risks.
- **Regulation 6, Rule 1 (Particulate Matter)**—This rule restricts emissions of PM darker than No. 1 on the Ringlemann Chart to less than 3 minutes in any 1 hour.
- **Regulation 6, Rule 6 (Prohibition of Trackout)**—This rule limits the quantity of PM in the atmosphere through control of trackout of solid materials onto paved public roads outside the boundaries of Large Bulk Material Sites, Large Construction Sites, and Large Disturbed Surface sites, including landfills.
- **Regulation 7 (Odorous Substances)**—This regulation establishes general odor limitations on odorous substances and specific emission limitations on certain odorous compounds.
- **Regulation 8, Rule 3 (Architectural Coatings)**—This rule limits the quantity of reactive organic gases (ROG) in architectural coatings.
- **Regulation 9, Rule 6 (Nitrogen Oxides Emission from Natural Gas–Fired Boilers and Water Heaters)**—This rule limits emissions of NO_X generated by natural gas–fired boilers.
- **Regulation 9, Rule 8 (Stationary Internal Combustion Engines)—**This rule limits emissions of NO_X and CO from stationary internal combustion engines of more than 50 horsepower.
- **Regulation 11, Rule 2 (Asbestos Demolition, Renovation, and Manufacturing)**—This rule controls emissions of asbestos to the atmosphere during demolition, renovation, milling, and manufacturing and establishes appropriate waste disposal procedures.

3.3.1.2 Monterey Bay Air Resources District

The MBARD has local air quality jurisdiction over projects in the NCCAB, including San Benito County. The MBARD has adopted CEQA emission thresholds in its *CEQA Air Quality Guidelines* (MBUAPCD 2008) to determine the level of significance of project-related emissions. Emissions that exceed the designated threshold levels are considered potentially significant and should be mitigated.

Through the attainment planning process, the MBARD has developed rules and regulations to regulate sources of air pollution. All projects located in San Benito County are subject to the MBARD regulations in effect at the time of construction. Specific regulations applicable to the

[7] Additional details regarding the applicable rules can be found at the BAAQMD website, http://www.baaqmd.gov/rules-and-compliance/current-rules.

project may involve diesel construction equipment emissions, fugitive dust, on-road haul truck emissions, and general permit requirements. The following list provides descriptions of MBARD rules that would be applicable to the project.[8]

- **Rule 200 (Permits)**—This rule identifies when permits are required and issued. It is anticipated the project would require an Authority to Construct and Permit to Operate, although additional permits may be needed.
- **Rule 207 (Review of New or Modified Sources)**—This rule provides for the review of new and modified stationary air pollution sources to meet provisions of the federal CAA.
- **Rule 400 (Visible Emissions)**—This rule provides limits for the visible emissions from sources within the district.
- **Rule 402 (Nuisances)—**This rule provides an explicit prohibition against sources creating public nuisances while operating within the district.
- **Rule 403 (Particulate Matter)**—This rule provides PM emission limits for sources operating within the district.
- **Rule 404 (Sulfur Compounds and Nitrogen Oxides)**—This rule provides limits for the emissions of sulfur compounds, NO_X, and NO_2 from sources within the district.
- **Rule 424 (National Emission Standards for Hazardous Air Pollutants)—**This rule provides clarity on the district's enforcement authority for the National Emission Standards for Hazardous Air Pollutants by incorporating those provisions of Parts 61 and 63, Chapter I, Title 40 of the C.F.R. into the rule by reference.
- **Rule 425 (Use of Cutback Asphalt)**—This rule limits the emissions of vapors of organic compounds from the use of cutback and emulsified asphalts.
- **Rule 426 (Architectural Coatings)**—This rule limits the emissions of ROGs from the use of architectural coatings.

3.3.1.3 San Joaquin Valley Air Pollution Control District

The SJVAPCD has local air quality jurisdiction over projects in the SJVAB including Merced County. The SJVAPCD prepared the *Guide for Assessing and Mitigating Air Quality Impacts* (GAMAQI) to assist lead agencies and project applicants in evaluating the potential air quality impacts of projects in the SJVAB (SJVAPCD 2015a). The GAMAQI provides SJVAPCD-recommended procedures for evaluating potential air quality impacts during the CEQA environmental review process.

SJVAPCD has specific air quality–related planning documents, rules, and regulations. The following regulations may be applicable to the project in Merced County.[9]

- **Rule 2010 (Permits Required)—**This rule requires any person constructing, altering, replacing or operating any source operation which emits, may emit, or may reduce emissions to obtain an Authority to Construct or a Permit to Operate.
- **Rule 2201 (New and Modified Stationary Source Review)**—This rule requires that sources not increase emissions above the specified thresholds.
- **Rule 2280 (Portable Equipment Registration)**—This rule requires portable equipment used at project sites for less than 6 consecutive months be registered with the SJVAPCD.

[8] Additional details regarding the applicable rules can be found at the MBARD website, http://mbard.org/programs-resources/permitting-engineering/rules-regulations/.

[9] Additional details regarding the applicable rules can be found at the SJVAPCD website, www.valleyair.org/rules/1ruleslist.htm.

- **Rule 4002 (National Emission Standards for Hazardous Air Pollutants)**—This rule incorporates by reference the National Emission Standards for Hazardous Air Pollutants from 40 C.F.R., Part 61, Chapter I, Subchapter C and the National Emission Standards for Hazardous Air Pollutants for Source Categories from 40 C.F.R., Part 63, Chapter I, Subchapter C.
- **Rule 4102 (Nuisance)**—This rule prohibits discharge from any source whatsoever such quantities of air contaminants or other materials which cause injury, detriment, nuisance, or annoyance to any considerable number of persons or to the public or which endanger the comfort, repose, health, or safety of any such person or the public or which cause or have a natural tendency to cause injury or damage to business or property.
- **Rule 4201 and Rule 4202 (Particulate Matter Concentration and Emission Rates)**—These rules provide PM emission limits for sources operating within the district.
- **Rule 4301 (Fuel-Burning Equipment)**—This rule limits the emissions from fuel-burning equipment whose primary purpose is to produce heat or power by indirect heat transfer.
- **Rule 4601 (Architectural Coatings)**—This rule limits VOC emissions from architectural coatings.
- **Rule 4641 (Cutback, Slow Cure, and Emulsified Asphalt, Paving, and Maintenance Operations)**—This rule limits VOC emissions by restricting the application and manufacturing of certain types of asphalt for paving and maintenance operations.
- **Rule 8011 (General Requirements—Fugitive Dust Emission Sources)**—This rule outlines requirements for implementation of control measures for fugitive dust emission sources.
- **Rule 9510 (Indirect Source Review)**—This rule outlines mitigation requirements for construction and operations emissions that exceed certain thresholds. The rule applies to any transportation project in which construction emissions equal or exceed 2 tons of NO_X or PM_{10} per year. Projects subject to Rule 9510 must submit an Air Impact Assessment application to the SJVAPCD prior to construction.

3.3.2 Metropolitan Transportation Commission

The Metropolitan Transportation Commission (MTC) serves as both the state-designated regional transportation agency and as the federally designated metropolitan planning organization for the Bay Area. Thus, it is responsible for regularly updating the RTP, a comprehensive blueprint for the development of mass transit, highway, airport, seaport, railroad, bicycle and pedestrian facilities. The MTC also screens requests from local agencies for state and federal grants for transportation projects to determine their compatibility with the plan.

3.3.3 Association of Bay Area Governments

The Association of Bay Area Governments (ABAG) serves as a regional planning body for the Bay Area. ABAG, MTC, and BAAQMD work closely to develop long-range plans that improve the environment and standard of living through a series of measures that link land use, transportation, and air quality. ABAG is responsible for maintaining the state-mandated SCS which links land use, transportation planning, and state funding. ABAG also develops demographic, economic, and project analyses for the region. ABAG also develops earthquake preparedness plans and green business development strategies and leads the San Francisco Bay Trail planning program and the San Francisco Estuary Project.

3.3.4 Association of Monterey Bay Area Governments

The Association of Monterey Bay Area Governments (AMBAG) serves as both a federally designated metropolitan planning organization and regional planning body for the North Central Coast. AMBAG performs metropolitan level transportation planning on behalf of the region. Among its many duties, AMBAG manages the region's transportation demand model and

prepares regional housing, population, and employment forecasts that are utilized in a variety of regional plans.

3.3.5 Council of San Benito County Governments

The Council of San Benito County Governments (San Benito COG) is San Benito County's regional transportation planning agency. San Benito COG plans for the long-term safety and transportation needs of San Benito County residents by improving highways, streets, roads, bicycle paths, bus service, and walkways. San Benito COG works closely with the County, the Cities of Hollister and San Juan Bautista, the California Department of Transportation (Caltrans), AMBAG, and other agencies to help improve travel in the region.

3.3.6 Merced County Association of Governments

The Merced County Association of Governments (MCAG) is the federally designated metropolitan planning organization for Merced County. MCAG comprises representatives from Merced County and the Cities of Atwater, Dos Palos, Gustine, Livingston, Los Banos, and Merced. As a regional transportation planning agency and metropolitan planning organization, MCAG is the primary transportation facilitator in Merced County.

3.3.7 Air Quality Plans

3.3.7.1 State Implementation Plan

Federal clean air laws require areas with unhealthy levels of O_3, inhalable PM, CO, NO_2, and SO_2 to develop plans, known as SIPs. SIPs are comprehensive plans that describe how an area will attain NAAQS. The 1990 amendments to the federal CAA set deadlines for attainment based on the severity of an area's air pollution problem.

SIPs are not single documents. They are a compilation of new and previously submitted plans, programs (such as monitoring, modeling, or permitting), district rules, state regulations, and federal controls. Many of California's SIPs rely on the same core set of control strategies, including emission standards for cars and heavy trucks, fuel regulations, and limits on emissions from consumer products. State law makes the CARB the lead agency for all purposes related to SIPs. Local air districts and other agencies, such as the Bureau of Automotive Repair and the Department of Pesticide Regulation, prepare SIP elements and submit them to the CARB for review and approval. The CARB forwards SIP revisions to the USEPA for approval and publication in the Fed. Reg. 40 C.F.R. Chapter I, Part 52, Subpart F, Section 52.220 lists all of the items that are included in the California SIP. At any one time, several California submittals are pending USEPA approval.

The following are the relevant regional SIP and air quality plans for the SFBAAB:

- 2001 San Francisco Bay Area Ozone Attainment Plan for the 1-Hour National Ozone Standard (BAAQMD 2001)
- 2017 Clean Air Plan: Spare the Air, Cool the Climate (BAAQMD 2017b)

The following are the relevant regional SIP and air quality plans for the NCCAB:

- 2005 Report on Attainment of the California Particulate Matter Standards in the Monterey Bay Region (MBUAPCD 2005)
- 2007 Federal Maintenance Plan for Maintaining the National Ozone Standard in the Monterey Bay Region (MBUAPCD 2007)
- 2012–2015 Air Quality Management Plan (MBUAPCD 2017)

The following are the relevant regional SIP and air quality plans for the SJVAB:

- 2007 PM_{10} Maintenance Plan and Request for Redesignation (SJVAPCD 2007a)
- 2007 Ozone Plan (SJVAPCD 2007b)
- 2013 Plan for the Revoked 1-Hour Ozone Standard (SJVAPCD 2013)

- 2015 Plan for the 1997 $PM_{2.5}$ Standard (SJVAPCD 2015b)
- 2016 Moderate Area Plan for the 2012 $PM_{2.5}$ Standard (SJVAPCD 2016a)
- 2016 Plan for the 2008 8-Hour Ozone Standard (SJVAPCD 2016b)
- 2018 Plan for the 1997, 2006, and 2012 $PM_{2.5}$ Standards (SJVAPCD 2018)

3.3.7.2 Transportation Plans and Programs

An RTP is a long-range plan that includes both long- and short-range strategies and actions that lead to the development of an integrated multimodal transportation system to address future transportation demand. Projects subject to transportation conformity are analyzed for air quality conformity with the SIP as components of RTPs and transportation improvement programs (TIP). RTPs address a region's growth, transportation goals, objectives, and policies for the next 25 years and identify the actions necessary to achieve those goals. TIPs provide a comprehensive listing of all surface transportation projects that are to receive federal funding, are subject to a federally required action, or are considered regionally significant for air quality conformity purposes. RTPs and TIPs relevant to the project are discussed in this section.

San Francisco Bay Area

In the Bay Area, the MTC is responsible for preparing RTPs and TIPs. On July 26, 2017, the MTC adopted the latest RTP for the area, *Plan Bay Area 2040*, which specifies how approximately $303 billion in anticipated federal, state, and local transportation funds will be spent in the nine-county Bay Area during the next 25 years (ABAG and MTC 2017).

The TIP includes improvements for transit; local roadway, state highway, bicycle, and pedestrian facilities; and other regionally significant, locally funded transportation projects in the nine-county Bay Area. The MTC prepares and adopts the TIP every 2 years. The current 2019 TIP covers fiscal years 2018–19 through 2021–22. It contains 500 projects totaling about $13.2 billion over a 4-year period.

The MTC prepares a transportation air quality conformity analysis when it amends or updates its long-range RTP or adds or deletes regionally significant nonexempt projects into the TIP. In 2018, a conformity analysis was finalized for the *Plan Bay Area 2040* and the 2019 TIP in accordance with USEPA transportation conformity regulations and the Bay Area Conformity SIP (Bay Area Air Quality Conformity Protocol).

San Benito County

The San Benito COG prepares a county-wide RTP every 4 years to set forth transportation policy over the next 20 years. The current RTP, *2040 San Benito Regional Transportation Plan*, was adopted June 21, 2018. The plan identifies nearly $1.8 billion in estimated transportation funding for projects and programs.

The San Benito COG also prepares the financially constrained TIP for San Benito County. The current *2016 Regional Transportation Improvement Program* was adopted on February 26, 2016. The conformity analysis for the 2018 RTP and 2016 TIP (revised) in accordance with USEPA transportation conformity regulations and the applicable SIPs was finalized in 2018.

Merced County

MCAG is responsible for preparing the RTP and TIP for transportation projects in Merced County. MCAG adopted the *2018 Regional Transportation Plan* on August 16, 2018, and adopted the *2018 Regional Improvement Program* on November 16, 2017. The final conformity assessment was adopted in August 2018.

3.3.7.3 Regional and Local Air Quality Policies

Table 3-2 outlines the policies related to air quality and GHG from regional and local plans that were considered in the preparation of this analysis. Relevant policies from some of the RTPs are included in this table.

Table 3-2 Regional and Local Plans and Policies

Plans and Policies	Summary
Regional	
Plan Bay Area (ABAG and MTC 2017)	The ABAG and the MTC adopted Plan Bay Area 2040 as the Bay Area's long-term regional transportation and land use blueprint in 2017. The following goals and objectives are relevant to the project: ▪ Target #1: Reduce per-capita CO_2 emissions from cars and light-duty trucks by 15 percent. ▪ Target #3: Reduce adverse health impacts associated with air quality, road safety and physical inactivity by 10%.
San Joaquin Valley Blueprint Planning Process Summary Report (2010)	The *San Joaquin Valley Blueprint Planning Process Summary Report* was prepared in 2010. The following goal is relevant to the project: ▪ Principle 12: Support actions that encourage environmental resource management.
Moving Forward 2035 Monterey Bay (2017)	The Association of Monterey Bay Area Governments adopted *Moving Forward 2035 Monterey Bay* as the region's long-term RTP in 2014 and amended it in 2017. The following policy is relevant to the project: ▪ Policy 3: Environment – Promote environmental sustainability and protect the natural environment.
2018 Regional Transportation Plan (2018)	The Merced County Association of Governments adopted the *2018 Regional Transportation Plan* as the County's long-term RTP in 2018. The following goals and objectives are relevant to the project: ▪ 8.1. Coordinate transportation planning with air quality planning at the technical and policy level.
Santa Clara County	
Santa Clara County General Plan (1994)	The *Santa Clara County General Plan* was adopted in 1994. The following goals and policies are relevant to the project: ▪ Policy C-TR 11 Santa Clara County shall participate in updating and implementing the Congestion Management Plan, the provisions of which as set forth by law: a. establish priority for air quality goals and objectives and development of alternatives to automobile travel; and b. allow additional road capacity to be created only when all feasible automobile travel demand measures have been implemented. ▪ Policy C-RC 80 Sub-regional/countywide planning for Santa Clara County should place major emphasis on the inter-related goals, strategies and policies for improving energy efficiency in transportation, air quality, and reducing traffic congestion.

Plans and Policies	Summary
City of Santa Clara	
City of Santa Clara 2010–2035 General Plan (2010)	The *City of Santa Clara 2010–2035 General Plan* was adopted in November 2010. The following goals and policies are relevant to the project: ▪ 5.10.2-P1 Support alternative transportation modes and efficient parking mechanisms to improve air quality. ▪ 5.10.2-P2 Encourage development patterns that reduce vehicle miles traveled and air pollution. ▪ 5.10.2-P3 Encourage implementation of technological advances that minimize public health hazards and reduce the generation of air pollutants. ▪ 5.10.2-P4 Encourage measures to reduce greenhouse gas emissions to reach 30 percent below 1990 levels by 2020. ▪ 5.10.2-P6 Require "Best Management Practices" for construction dust abatement. ▪ 5.8.1-P4 Expand transportation options and improve alternate modes that reduce greenhouse gas emissions. ▪ 5.10.3-P15 Explore opportunities for alternative energy "fueling stations" and promote participation in shuttle services that use new technology vehicles to reduce greenhouse gas emissions.
City of San Jose	
Envision: San José 2040 General Plan (2011)	The *Envision: San José 2040 General Plan* was adopted in 2011. The following goals and policies are relevant to the project: ▪ MS-1.7 Encourage retrofits for existing buildings throughout San José to use green building principles in order to mitigate the environmental, economic, and social impact of those buildings, to achieve greenhouse gas reductions, and to improve air and water quality. ▪ MS-4.1 Promote the use of building materials that maintain healthful indoor air quality in an effort to reduce irritation and exposure to toxins and allergens for building occupants. ▪ MS-4.2 Encourage construction and pre-occupancy practices to improve indoor air quality upon occupancy of the structure. ▪ MS-10.1 Assess projected air emissions from new development in conformance with the Bay Area Air Quality Management District (BAAQMD) CEQA Guidelines and relative to state and federal standards. Identify and implement feasible air emission reduction measures. ▪ MS-10.2 Consider the cumulative air quality impacts from proposed developments for proposed land use designation changes and new development, consistent with the region's Clean Air Plan and State law. ▪ MS-10.3 Promote the expansion and improvement of public transportation services and facilities, where appropriate, to both encourage energy conservation and reduce air pollution. ▪ MS-10.4 Encourage effective regulation of mobile and stationary sources of air pollution, both inside and outside of San José. In particular, support Federal and State regulations to improve automobile emission controls. ▪ MS-10.7 Encourage regional and statewide air pollutant emission reduction through energy conservation to improve air quality.

Plans and Policies	Summary
	▪ MS-10.8 Minimize vegetation removal required for fire prevention. Require alternatives to discing, such as mowing, to the extent feasible. Where vegetation removal is required for property maintenance purposes, encourage alternatives that limit the exposure of bare soil. ▪ MS-10.9 Foster educational programs about air pollution problems and solutions. ▪ MS-11.2 For projects that emit toxic air contaminants, require project proponents to prepare health risk assessments in accordance with BAAQMD-recommended procedures as part of environmental review and employ effective mitigation to reduce possible health risks to a less than significant level. Alternatively, require new projects (such as, but not limited to, industrial, manufacturing, and processing facilities) that are sources of TACs to be located an adequate distance from residential areas and other sensitive receptors. ▪ MS-11.3 Review projects generating significant heavy duty truck traffic to designate truck routes that minimize exposure of sensitive receptors to TACs and particulate matter. ▪ MS-11.4 Encourage the installation of appropriate air filtration at existing schools, residences, and other sensitive receptor uses adversely affected by pollution sources. ▪ MS-11.5 Encourage the use of pollution absorbing trees and vegetation in buffer areas between substantial sources of TACs and sensitive land uses. ▪ MS-13.1 Include dust, particulate matter, and construction equipment exhaust control measures as conditions of approval for subdivision maps, site development and planned development permits, grading permits, and demolition permits. At minimum, conditions shall conform to construction mitigation measures recommended in the current BAAQMD CEQA Guidelines for the relevant project size and type. ▪ MS-13.2 Construction and/or demolition projects that have the potential to disturb asbestos (from soil or building material) shall comply with all the requirements of the California Air Resources Board's air toxics control measures (ATCMs) for Construction, Grading, Quarrying, and Surface Mining Operations. ▪ MS-13.3 Require subdivision designs and site planning to minimize grading and use landform grading in hillside areas. ▪ EC-7.7 Determine for any development or redevelopment site that is within 1,000 feet of a known, suspected, or likely geographic ultramafic rock unit (as identified in maps developed by the Department of Conservation – Division of Mines and Geology) or any other known or suspected locations of serpentine or naturally occurring asbestos, if naturally occurring asbestos exists and, if so, comply with the Bay Area Air Quality Management District's Asbestos Air Toxic Control Measure requirements. ▪ TR-1.8 Actively coordinate with regional transportation, land use planning, and transit agencies to develop a transportation network with complementary land uses that encourage travel by bicycling, walking and transit, and ensure that regional greenhouse gas emission standards are met.
Midtown Specific Plan (1992)	The *Midtown Specific Plan* was adopted in 1992. The following goals and policies are relevant to the project: ▪ Policy 4.3: Future development should incorporate energy-conserving devices to promote conservation.
Diridon Station Area Plan (2014)	The *Diridon Station Area Plan* was adopted in 2014. No goals and policies are directly relevant to the air quality or greenhouse gas analysis of the project.

Plans and Policies	Summary
Communications Hill Specific Plan (1992)	The *Communications Hill Specific Plan* was adopted in 1992. The following goals and policies are relevant to the project: ▪ Minimize the potential adverse impacts of the Communication Hill area development on the immediate surrounding neighborhood.
City of Morgan Hill	
Morgan Hill 2035 General Plan (2016)	The *Morgan Hill 2035 General Plan* was adopted in 2016. The following goals and policies are relevant to the project: ▪ Policy NRE-10.1 Regional and Subregional Cooperation. Cooperate with regional agencies in developing and implementing air quality management plans. Support subregional coordination with other cities, counties, and agencies in the Santa Clara Valley and adjacent areas to address land use, jobs/housing balance, and transportation planning issues as a means of improving air quality. ▪ Policy NRE-10.2 State and Federal Regulation. Encourage effective regulation of mobile and stationary sources of air pollution and support State and federal regulations to improve automobile emission controls. ▪ Policy NRE-10.3 Automobile Emissions. Encourage the use of and infrastructure for alternative fuel, hybrid, and electric vehicles. Encourage new and existing public and private development to include electric vehicle charging stations. ▪ Policy NRE-10.4 Reduced Automobile Use. To reduce air pollution the frequency and length of automobile trips and the amount of traffic congestion by controlling sprawl, promoting infill development, and encouraging mixed uses and higher density development near transit. Support the expansion and improvement of alternative modes of transportation. Encourage development project designs that protect and improve air quality and minimize direct and indirect air pollutant emissions by including components that reduce vehicle trips. ▪ Policy NRE-11.2 TACs and Existing Sensitive Uses. Encourage the installation of appropriate air filtration mechanisms at existing schools, residences, and other sensitive receptors adversely affected by existing or proposed pollution sources. ▪ Policy NRE-11.3 Health Risk Assessments. For proposed development that emits toxic air contaminants, require project proponents to prepare health risk assessments in accordance with Bay Area Air Quality Management District procedures as part of environmental review and implement effective mitigation measures to reduce potential health risks to less-than-significant levels. Alternatively, require these projects to be located an adequate distance from residences and other sensitive receptors to avoid health risks. Consult with the Bay Area Air Quality Management District to identify stationary and mobile toxic air contaminant sources and determine the need for and requirements of a health risk assessment for proposed developments. ▪ Policy NRE-11.4 Truck Routes. For development projects generating significant heavy duty truck traffic, designate truck routes that minimize exposure of sensitive receptors to toxic air contaminants and particulate matter. ▪ Policy NRE-11.5 Truck Idling. For development projects generating significant truck traffic, require signage to remind drivers that the State truck idling law limits truck idling to five (5) minutes. ▪ Policy NRE-11.5 Truck Idling. For development projects generating significant truck traffic, require signage to remind drivers that the State truck idling law limits truck idling to five (5) minutes. ▪ Policy NRE-11.6 Vegetation Buffers. Encourage the use of pollution-absorbing trees and vegetation in buffer areas between substantial sources of toxic air contaminants and sensitive receptors.

Plans and Policies	Summary
	▪ Policy NRE-12.1 Best Practices. Requirement that development projects implement best management practices to reduce air pollutant emissions associated with construction and operation of the project. ▪ Policy NRE-12.2 Conditions of Approvals. Include dust, particulate matter, and construction equipment exhaust control measures as conditions of approval for subdivision maps, site development and planned development permits, grading permits, and demolition permits. At a minimum, conditions shall conform to construction mitigation measures recommended in the current Bay Area Air Quality Management District CEQA Guidelines. ▪ Policy NRE-12.3 Control Measures. Require construction and demolition projects that have the potential to disturb asbestos (from soil or building material) to comply with all the requirements of the California Air Resource Board's air toxics control measures (ATCMs) for Construction, Grading, Quarrying, and Surface Mining Operations. ▪ Policy NRE-12.4 Grading. Require subdivision designs and site planning to minimize grading and use landform grading in hillside areas. ▪ Policy NRE-15.1 Greenhouse Gas Emission Reduction Targets. Maintain a greenhouse gas reduction trajectory that is consistent with the greenhouse gas reduction targets of Executive Orders B-30-15 (40 percent below 1990 levels by 2030) and S-03-05 (80 percent below 1990 levels by 2050) to ensure the City is consistent with statewide efforts to reduce greenhouse gas emissions. ▪ Policy NRE-15.2 Linking Land Use and Transportation. Encourage land use and transportation patterns that reduce dependence on automobiles. ▪ Policy NRE-15.3 Climate Action Plan. Utilize policies in this General Plan denoted with the green leaf symbol as the City's greenhouse gas emissions reduction strategy. ▪ Policy NRE-15.4 Sustainable Land Use. Promote land use patterns that reduce the number and length of motor vehicle trips. ▪ Policy NRE-15.10 VMT Reduction. Continue to work with the Santa Clara Valley Transportation Authority on regional transportation solutions that will reduce vehicle miles traveled and greenhouse gas emissions.
City of Gilroy	
City of Gilroy 2002–2020 General Plan (2002)	The *City of Gilroy 2002–2020 General Plan* was adopted in 2002. The following goals and policies are relevant to the project: ▪ Policy 21.01 "Sensitive Receptors." Use land use planning and project siting to separate air pollution sources (such as freeways, arterials, industrial sites, etc.) from residential areas and other "sensitive receptors" (such as schools, hospital, and nursing homes) that would be adversely affected by close proximity to air pollutants. ▪ Policy 21.02 Landscaping to Reduce Pollutants. Promote the use of trees and plants in landscaping to reduce air pollutant levels. ▪ Policy 21.04 Regional Collaboration. Cooperate with the Bay Area Air Quality Management District and other agencies that deal with issues related to air quality (e.g., the Metropolitan Transportation Commission and the Association of Bay Area Governments) to develop and implement regional air quality strategies. Also, support subregional coordination with other cities, counties and agencies in Santa Clara Valley and adjacent areas to address land use, jobs/housing balance, and transportation planning issues as a means of improving air quality. ▪ Policy 21.05 Air Quality Impacts from Construction Activity. Reduce the air quality impacts associated with construction activity by reducing the exhaust emissions through appropriate mitigation actions.

Plans and Policies	Summary
	▪ Policy 21.06 Traffic Control Measures. Implement the Transportation Control Measures recommended by the Bay Area Air Quality Management District in the 2000 Clean Air Plan to reduce pollutant emissions. ▪ Policy 12.09 LOS and Air Quality. Maintain the City's Standard Level of Service whenever feasible to minimize traffic congestion and thereby minimize exposure to carbon monoxide, since vehicles generate less air pollutant emissions at higher speed. ▪ Policy 14.01 Non-Auto Modes of Travel. Emphasize non-auto travel modes of transportation as a key strategy for achieving air quality goals. For example, encourage bicycle riding to school from an early age by providing safer bikeways between residential areas and schools and encourage the schools to provide secured bike racks and/or lockers.
Downtown Gilroy Specific Plan (2005)	The *Downtown Gilroy Specific Plan* was adopted in 2005. No goals and policies are directly relevant to the air quality or greenhouse gas analysis of the project.
San Benito County	
San Benito County 2035 General Plan (2015)	The *San Benito County 2035 General Plan* was adopted in 2015. The following goals and policies are relevant to the project: ▪ HS-5.1 New Development. The County shall use the CEQA process to ensure development projects incorporate feasible mitigation measures to reduce construction and operational air quality emissions, and consult with the Monterey Bay Unified Air Pollution Control District early in the development review process. ▪ HS-5.2 Sensitive Land Use Locations. The County shall ensure adequate distances between sensitive land uses and facilities or operations that may produce toxic or hazardous air pollutants or substantial odors. ▪ HS-5.3 Early Coordination with the Air Quality Control District. The County shall notify and coordinate with the Monterey Bay Unified Air Pollution Control District when industrial developments are proposed within the county to ensure applicants comply with applicable air quality regulations and incorporate design features and technologies to reduce air emissions. ▪ HS-5.4 PM10 Emissions from Construction. The County shall require developers to reduce particulate matter emissions from construction (e.g., grading, excavation, and demolition) consistent with standards established by the Monterey Bay Unified Air Pollution Control District. ▪ HS-5.6 New Construction Mitigation. The County shall work in coordination with the Monterey Bay Unified Air Pollution Control District to minimize air emissions from construction activities associated with proposed development. ▪ HS-5.7 Greenhouse Gas Emission Reductions. The County shall promote greenhouse gas emission reductions by supporting carbon efficient farming methods (e.g., methane capture systems, no-till farming, crop rotation, cover cropping); supporting the installation of renewable energy technologies; and protecting grasslands, open space, oak woodlands, riparian forest and farmlands from conversion to urban uses. ▪ HS-5.8 GHG Reduction Targets. The County acknowledges that the state endeavors to achieve 1990 greenhouse gas (GHG) emission levels, and establish a long-term goal to reduce GHG emissions by 80 percent below 1990 levels by 2050. The County will encourage projects that support these goals, recognizing that these goals can be met only if the state succeeds in decarbonizing its fuel supply. ▪ AD-2.5 Air Quality Management Coordination. The County shall continue to coordinate with the Monterey Bay Unified Air Pollution Control District (MBUAPCD) and affected agencies and neighboring jurisdictions in the North Central Coast Air

Plans and Policies	Summary
	Basin to ensure regional cooperation on cross-jurisdictional and regional transportation and air quality issues, and to establish parallel air quality programs and implementation measures. ▪ PFS-2.1 Efficient Operations. The County shall maintain facilities and service standards and conduct operations in a manner that meets community needs in an efficient manner, conserves resources, and reduces the County's contribution to greenhouse gas emissions.
Merced County	
2030 Merced County General Plan (2013)	The *2030 Merced County General Plan* was adopted in 2013. The following goals and policies are relevant to the project: ▪ Policy ED-1.7: Improving Merced County's Quality of Life (SO/PI). Economic development efforts shall include consideration of improving air quality, developing an educated workforce, promoting safe/crime-free communities, protecting water quality, and increasing recreational opportunities as a means to improve the quality of life for residents and workers and to attract new industries to the County. ▪ Policy LU-10.9: Air Quality Management Coordination (IGC). Coordinate with the San Joaquin Valley Air Pollution Control District and affected agencies and neighboring jurisdictions in the San Joaquin Valley Air Basin to ensure regional cooperation on cross-jurisdictional and regional transportation and air quality issues, and to establish parallel air quality programs and implementation measures, such as trip reduction ordinances and indirect source programs. ▪ Policy LU-10.10: San Joaquin Valley Air Pollution Control District Consultation (IGC). Consult with the San Joaquin Valley Air Pollution Control District during CEQA review for discretionary projects that have the potential for causing adverse air quality impacts. Ensure that development projects are submitted to the District for CEQA comments and review of air quality analysis. ▪ Policy CIR-1.3: Transportation Efficiency (RDR). Encourage transportation programs that result in more efficient energy use, reduce greenhouse gas emissions and noise levels, and improve air quality. ▪ Policy AQ-1.1: Energy Consumption Reduction (RDR). Encourage new residential, commercial, and industrial development to reduce air quality impacts from energy consumption. ▪ Policy AQ-1.6: Air Quality Improvement (SO). Support and implement programs to improve air quality throughout the County by reducing emissions related to vehicular travel and agricultural practices. ▪ Policy AQ-2.1: Air Quality Plan Compliance (RDR). Require all development projects to comply with applicable regional air quality plans and policies. ▪ Policy AQ-2.3: Cumulative Impacts (RDR). Encourage the reduction of cumulative air quality impacts produced by projects that are not significant by themselves, but result in cumulatively significant impacts in combination with other development. ▪ Policy AQ-2.4: Mitigation (RDR). Require that local and regional air quality impacts identified during CEQA review for projects reviewed and approved by the County are consistently and fairly mitigated. ▪ Policy AQ-2.5: Innovative Mitigation Measures (RDR, IGC, JP). Encourage innovative mitigation measures and project redesign to reduce air quality impacts by coordinating with the San Joaquin Valley Air Pollution Control District, project applicants, and other interested parties. ▪ Air Quality Element Goal AQ-3. Improve air quality through improved public facilities and operations and to serve as a model for the private sector.

Plans and Policies	Summary
	▪ Policy AQ-4.6: Non-Motorized Transportation (RDR). Encourage non-motorized transportation corridors within and between communities. ▪ Policy AQ-4.7: Planning Integration (RDR). Require land use, transportation, and air quality planning to be integrated for the most efficient use of resources and a healthier environment. ▪ Policy AQ-5.1: Residential Buffers (RDR). Require effective buffers between residential and other sensitive land uses, and nonresidential land uses that generate hazardous air emissions such as highways (e.g., I-5 and SR-99), trucking centers, gasoline dispensing facilities, and dry cleaners. Effective buffers shall be determined by requiring consultation with the SJVAPCD for any project that may have a health risk impact, including those projects that would otherwise appear to be exempt from CEQA requirements.

3.3.8 Climate Action Plans

A number of cities in the RSA have adopted or are in the process of developing climate action plans (CAP), GHG reduction plans, or equivalent documents aimed at reducing local GHG emissions. Jurisdictions with adopted or in-development CAPs or GHG reduction plans for either municipal operations, community activities, or both include Santa Clara County and the Cities of Santa Clara, San Jose, Gilroy, and Morgan Hill. These plans all call for reductions in GHG emissions below current levels and actions to reduce VMT and associated transportation emissions. All plans include increased transit service as a key strategy in reducing local GHG emissions.

4 POLLUTANTS OF CONCERN

Three general classes of air pollutants are of concern for the project—criteria pollutants, TACs, and GHGs. Criteria pollutants are those pollutants for which the USEPA and the State of California have set ambient air quality standards. (For analysis purposes, these pollutants include chemical precursors of compounds for which ambient standards have been set.) TACs of concern for the project are nine MSATs identified by the USEPA as having significant contributions from mobile sources—acetaldehyde, acrolein, benzene, 1,3-butadiene, DPM and diesel exhaust organic gases, ethylbenzene, formaldehyde, naphthalene, and polycyclic organic matter. GHGs are gaseous compounds that limit the transmission of radiated heat from the Earth's surface to the atmosphere. GHGs include CO_2, CH_4, N_2O, hydrofluorocarbons, perfluorocarbons, SF_6, and other fluorinated gases, including nitrogen trifluoride and hydrofluoroether.

4.1 Criteria Pollutants

Criteria pollutants are pollutants for which federal and state ambient air quality standards have been established to protect public health and welfare (Chapter 3). The sources of these pollutants, their effects on human health and the nation's welfare, and their final deposition in the atmosphere vary considerably. The following sections provide a brief description of each criteria pollutant.

4.1.1 Ozone

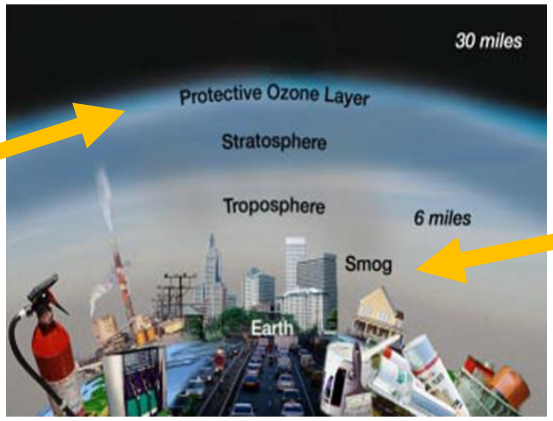
O_3 is a colorless toxic gas. As illustrated on Figure 4-1, O_3 is found in both the Earth's upper and lower atmosphere. In the upper atmosphere, O_3 is a naturally occurring gas that helps to prevent the sun's harmful ultraviolet rays from reaching the Earth. Substantial O_3 formation generally requires a stable atmosphere with strong sunlight; therefore, high levels of O_3 are generally a concern in the summer.

Definition of O_3

O_3 is a colorless toxic gas found in the Earth's upper and lower atmospheric levels. In the upper atmosphere, O_3 is naturally occurring and helps to prevent the sun's harmful ultraviolet rays from reaching the earth. In the lower atmosphere, O_3 is human-made. Although O_3 is not directly emitted, it forms in the lower atmosphere through a chemical reaction between hydrocarbons and oxides of nitrogen, also referred to as VOC and NO_X, which are emitted from industrial sources and from automobiles.

In the lower atmosphere, O_3 is largely human generated. Although O_3 is not directly emitted, it forms in the lower atmosphere through a chemical reaction between certain hydrocarbons, referred to as VOCs and NO_X that are emitted from industrial sources and motor vehicles. Hydrocarbons are compounds composed primarily of hydrogen and carbon atoms. Total organic gas and ROGs are the two classes of hydrocarbons that the CARB inventories. ROGs have relatively high photochemical reactivity. The major source of ROGs is the incomplete combustion of fossil fuel in internal combustion engines. Other sources of ROGs include evaporative emissions associated with paints and solvents, application of asphalt paving, and household consumer products. ROGs do not directly cause effects on human health, but they cause effects by reactions of ROGs to form secondary pollutants. ROGs are also transformed into organic aerosols in the atmosphere, contributing to higher levels of fine PM and lower visibility. The CARB uses the term *ROG* for air quality analysis and defines it the same as the federal term *VOC*. In this analysis, ROG is assumed to be equivalent to VOC.

Too little ozone there… Many popular consumer products like air conditioners and refrigerators involve chlorofluorocarbons or halons during either manufacture or use. Over time, these chemicals damage the earth's protective ozone layer.



Too much ozone here... Cars, trucks, power plants, and factories all emit air pollution that forms ground-level ozone, a primary component of smog.

Source: USEPA 2003

Figure 4-1 Ozone in the Atmosphere

O_3 is the main ingredient of smog. Ground-level O_3 causes health problems because it irritates the mucous membranes, damages lung tissue, reduces lung function, and sensitizes the lungs to other irritants. O_3-related health effects also include respiratory symptoms, aggravation of asthma, increased hospital and emergency room visits, increased asthma medication usage, and a variety of other respiratory-related effects. There is also evidence that short-term exposure to O_3 directly or indirectly contributes to cardiopulmonary-related mortality. In addition, O_3 can damage vegetation by inhibiting its growth. Because O_3 is not directly emitted, potential O_3 effects are assessed by examining the changes in VOC and NO_X emissions for the project on regional and statewide levels.

4.1.2 Particulate Matter

PM pollution is composed of solid particles or liquid droplets that are small enough to remain suspended in the air. In general, PM pollution can include dust, soot, and smoke, which can be irritating, but usually are not toxic. It can also include salts, acids, and metals. However, PM pollution can include substances that are highly toxic. Of particular concern are those particles that have diameters equal to or smaller than 10 microns (µm) (PM_{10})—about 1/7 the thickness of a human hair—or 2.5 µm ($PM_{2.5}$), approximately 1/28 the thickness of a human hair (Figure 4-2). PM can be emitted directly from a source or can form when gases emitted undergo chemical reactions in the atmosphere.

Definition of PM_{10} and $PM_{2.5}$

PM_{10} refers to PM less than 10 microns in diameter, about 1/7th the thickness of a human hair. PM pollution consists of small liquid and solid particles floating in the air, which can include smoke, soot, dust, salts, acids, and metals.

PM also forms when gases emitted from motor vehicles undergo chemical reactions in the atmosphere.

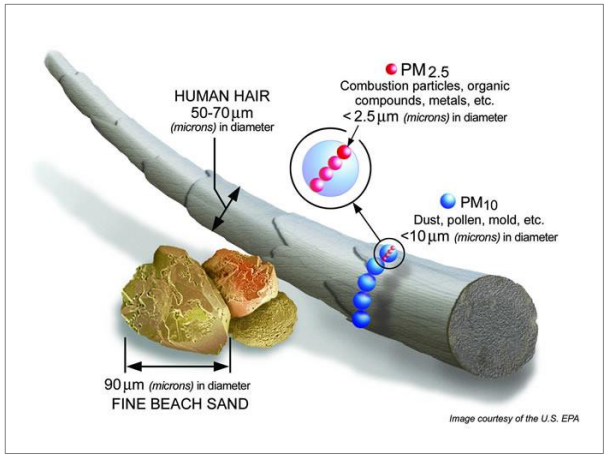
$PM_{2.5}$ is a subset of PM_{10} and refers to particulates that are 2.5 microns or less in diameter, roughly 1/28th the diameter of a human hair.

Major sources of PM_{10} include motor vehicles; wood-burning stoves and fireplaces; dust from construction, landfills, and agriculture; wildfires and brush/waste burning; industrial sources; windblown dust from open lands; and atmospheric chemical and photochemical reactions. These suspended particulates produce haze and reduce visibility.

A small portion of PM is the product of fuel combustion processes. However, the combustion of fossil fuels (by motor vehicles, power generation, and industrial facilities) accounts for a significant portion of $PM_{2.5}$ pollution. $PM_{2.5}$ also results from fuel combustion in residential

fireplaces and wood stoves. In addition, $PM_{2.5}$ can be formed in the atmosphere from gases such as SO_2, NO_X, and VOCs.

The main health effect of airborne PM is on the respiratory system. Both PM_{10} and $PM_{2.5}$ can penetrate the human respiratory system's natural defenses and damage the respiratory tract when inhaled. Both tend to collect in the upper portion of the respiratory system, but $PM_{2.5}$ or smaller particles can penetrate deeper into the lungs and damage lung tissues. The effects of PM_{10} and $PM_{2.5}$ emissions for the project are examined on a localized (i.e., microscale) basis, on a regional basis, and on a statewide basis.



Source: USEPA 2015c

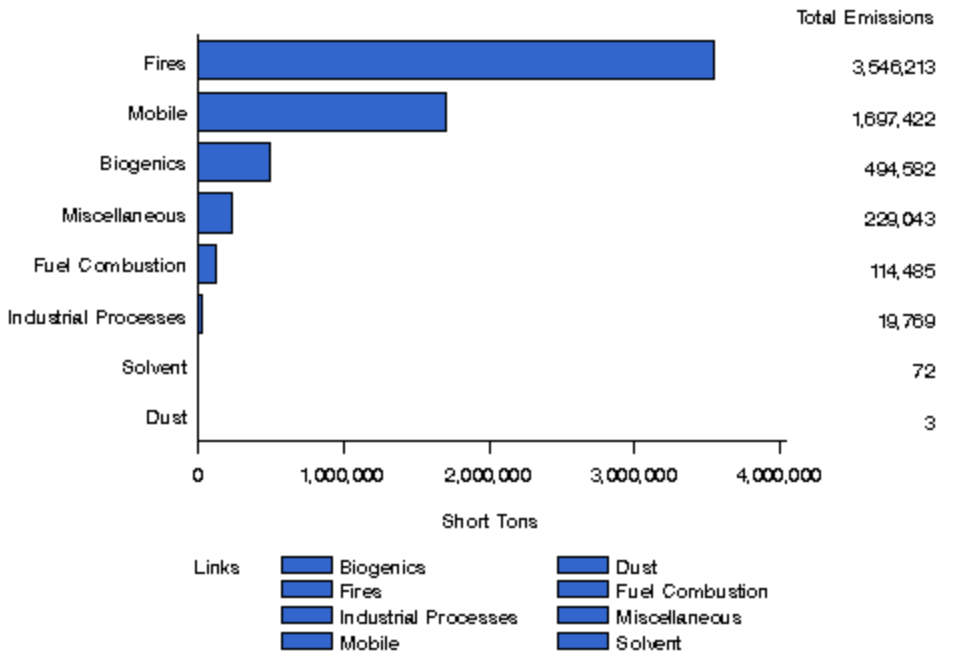
Figure 4-2
Relative Particulate Matter Size

4.1.3 Carbon Monoxide

CO is a colorless gas that interferes with the transfer of oxygen in the bloodstream to the brain. CO is emitted almost exclusively from the incomplete combustion of fossil fuels. As illustrated on Figure 4-3, on-road motor-vehicle exhaust is the primary source of CO in California. In cities, 85 to 95 percent of all CO emissions may come from motor-vehicle exhaust. Prolonged exposure to high levels of CO can cause headaches, drowsiness, loss of equilibrium, and heart disease. CO levels are generally highest in the colder months when inversion conditions (i.e., warmer air traps colder air near the ground) are more frequent. CO concentrations can vary greatly over relatively short distances. Relatively high concentrations of CO are typically found near congested intersections, along heavily used roadways carrying slow-moving traffic, and in areas where atmospheric dispersion is inhibited by urban street canyon conditions. The effects of CO emissions for the project are examined on a localized (i.e., microscale) basis, on a regional basis, and on a statewide basis.

Definition of CO

CO is a colorless gas that interferes with the transfer of oxygen to the brain. CO emits almost exclusively from the incomplete combustion of fossil fuels. On-road motor-vehicle exhaust is the primary source of CO.



Source: USEPA 2017

Figure 4-3 Sources of Carbon Monoxide in California (2014)

4.1.4 Nitrogen Dioxide

NO_2 is a brownish gas that irritates the lungs. It can cause breathing difficulties at high concentrations. NO_2 is one of a group of highly reactive gases known as oxides of nitrogen, or nitrogen oxides. NO_2 can be emitted directly or formed through a reaction between nitric oxide emissions and atmospheric oxygen. NO_2 also contributes to the formation of PM_{10}. At atmospheric concentrations, NO_2 is only potentially irritating. At high concentrations, the result is a brownish-red cast to the atmosphere and reduced visibility. There is some indication of a relationship between NO_2 and chronic (long-term) pulmonary fibrosis. Localized effects of NO_2 are analyzed relevant to the NAAQS and CAAQS.

4.1.5 Lead

Pb is a stable element that persists and accumulates in the environment and in animals. Its principal effects on humans are on the blood-forming, nervous, and renal systems. Pb levels from mobile sources in the urban environment have decreased significantly because of the federally mandated switch to Pb-free gasoline, and they are expected to continue to decrease. An analysis of the effects of Pb emissions from transportation projects is therefore not warranted and has not been conducted for the project.

4.1.6 Sulfur Dioxide

SO_2 is a gas produced by combustion of high-sulfur fuels. The main sources of SO_2 are coal and oil used in power stations, industry, and domestic heating. Industrial chemical manufacturing is another source of SO_2. SO_2 is an irritant that attacks the throat and lungs. It can cause acute respiratory symptoms and diminished ventilator function in children. SO_2 can also cause plant leaves to turn yellow and can corrode iron and steel. Although heavy-duty diesel vehicles emit SO_2, USEPA regulations have greatly decreased the sulfur content of diesel fuel and gasoline in recent years. Transportation sources contribute only a small fraction of total SO_2 emissions, and the USEPA and other regulatory agencies do not consider transportation sources to be significant

sources of this pollutant. Nevertheless, consistent with applicable air district guidance, the effects of changes in SO_2 emissions for the project are examined on regional and statewide levels.

4.2 Toxic and Noncriteria Pollutants

A TAC is defined by California law as an air pollutant that "may cause or contribute to an increase in mortality or an increase in serious illness, or which may pose a present or potential hazard to human health." The USEPA uses the term HAP in a similar sense. Controlling air toxic emissions became a national priority with the passage of the CAA, in which Congress mandated that the USEPA regulate 188 air toxics, also known as HAPs. TACs can be emitted from stationary and mobile sources. The effects of TACs and other noncriteria pollutants for the project are examined on a local level.

4.2.1 Asbestos

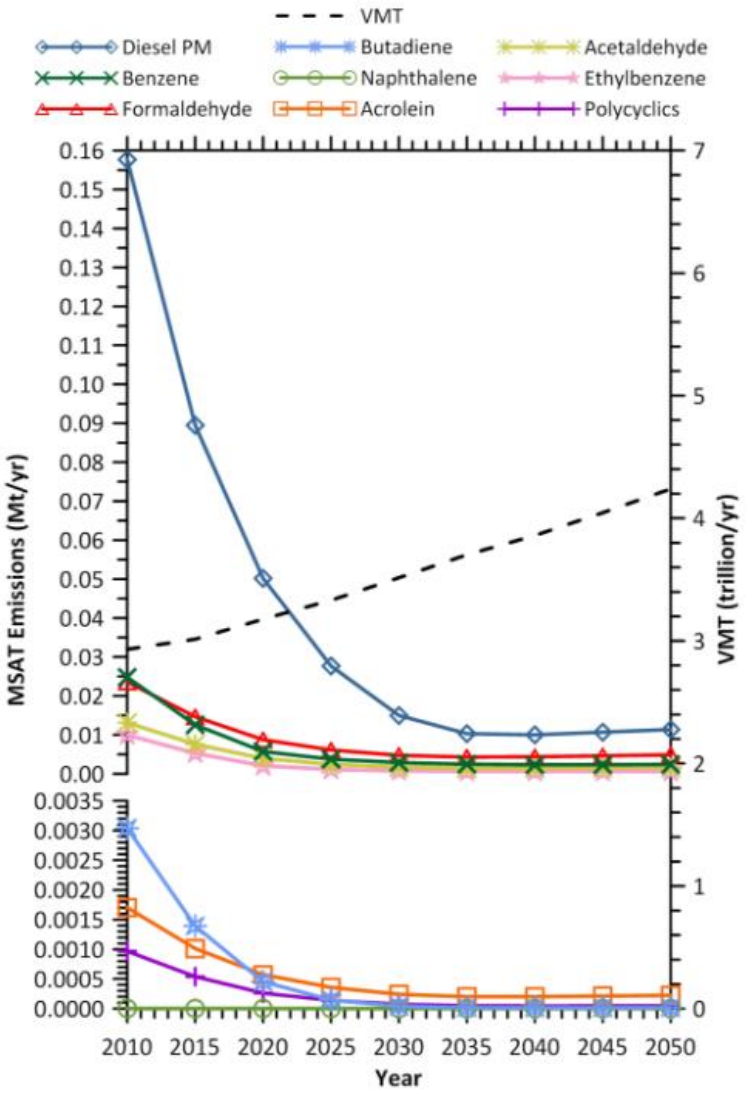
Asbestos deposits from brake wear may be present on surfaces and in the ambient air along the HSR alignment. In addition, asbestos-containing materials may have been used in constructing buildings that would be demolished. Asbestos minerals occur in rocks and soil (known as NOA) as the result of natural geologic processes, often in veins near earthquake faults in the coastal ranges and foothills of the Sierra Nevada and in other areas of California. NOA most commonly occurs in ultramafic rock (i.e., igneous and metamorphic rock with low silica content) that has undergone partial or complete alteration to serpentine rock (or serpentinite) and often contains chrysotile asbestos. In addition, another form of asbestos, tremolite, is associated with ultramafic rock, particularly near geologic faults.

Natural weathering or human disturbance can break NOA down to microscopic fibers, easily suspended in air. When inhaled, these thin fibers irritate tissues and resist the body's natural defenses. Chronic inhalation exposure to asbestos in humans can lead to asbestosis, which is a diffuse fibrous scarring of the lungs. Symptoms of asbestosis include shortness of breath, difficulty in breathing, and coughing. Asbestosis is a progressive disease (i.e., the severity of symptoms tends to increase with time, even after the exposure has stopped). In severe cases, this disease can lead to death caused by impairment of respiratory function. A large number of occupational studies have reported that exposure to asbestos by inhalation can cause lung cancer and mesothelioma, which is a rare cancer of the membranes lining the abdominal cavity and surrounding internal organs. The USEPA considers asbestos to be a human carcinogen (i.e., cancer-causing agent) (USEPA 2000). The effects of asbestos for the project are examined on regional and local levels.

4.2.2 Mobile Source Air Toxics

The USEPA has assessed an expansive list of air toxics in its 2007 Rule on the Control of Hazardous Air Pollutants from Mobile Sources and identified a group of 93 compounds emitted from mobile sources that are listed in its Integrated Risk Information System.

Under the 2007 rule, the USEPA sets standards on fuel composition, vehicle exhaust emissions, and evaporative losses from portable containers. Using USEPA's MOVES2014a model, as shown on Figure 4-4, the FHWA estimates that even if VMT increases by 45 percent from 2010 to 2050 as forecast, a combined reduction of 91 percent in the total annual emissions for the priority MSAT is projected for the same period.



Source: FHWA 2016

Trends for specific locations may be different, depending on locally derived information representing vehicle miles traveled, vehicle speeds, vehicle mix, fuels, emission-control programs, meteorology, and other factors.

Figure 4-4 Projected National Mobile Source Air Toxics Emission Trends (2010–2050) for Vehicles Operating on Roadways, Based on USEPA's MOVES2014a Model Assessment (USEPA 2015d)

The USEPA identified nine compounds with significant contributions from mobile sources that are among the national- and regional-scale cancer risk drivers from its National Air Toxics Assessment (USEPA 2015d). These are acrolein, benzene, 1,3-butadiene, acetaldehyde, DPM, ethylbenzene, formaldehyde, naphthalene, and polycyclic organic matter. While the FHWA considers these the priority MSATs, the list is subject to change and may be adjusted in consideration of future USEPA rules. The effects of MSATs for the project are examined on a regional and local level. The following paragraphs describe these MSATs (Authority and FRA 2012b).

Acrolein is a colorless-to-yellow liquid that burns easily, is readily volatilized, and has a disagreeable odor. It is present as a product of incomplete combustion in the exhausts of stationary equipment (e.g., boilers and heaters) and mobile sources. It is also a secondary

pollutant formed through the photochemical reaction of VOCs and NO_X in the atmosphere. Acrolein is considered to have high acute toxicity, and it causes upper respiratory tract irritation and congestion in humans. The major effects from chronic (long-term) inhalation exposure to acrolein in humans consist of general respiratory congestion and eye, nose, and throat irritation. No information is available on the reproductive, developmental, or carcinogenic effects of acrolein in humans. The USEPA considers acrolein data inadequate for an assessment of human carcinogenic potential.

Benzene is a volatile, colorless, highly flammable liquid with a sweet odor. Most of the benzene in ambient air is from incomplete combustion of fossil fuels and evaporation from gasoline service stations. Acute inhalation exposure to benzene causes neurological symptoms, such as drowsiness, dizziness, headaches, and unconsciousness in humans. Chronic inhalation of certain levels of benzene causes disorders in the blood in humans. Benzene specifically affects bone marrow (the tissues that produce blood cells). Aplastic anemia, excessive bleeding, and damage to the immune system (by changes in blood levels of antibodies and loss of white blood cells) may develop. Available human data on the developmental effects of benzene are inconclusive because of concomitant exposure to other chemicals, inadequate sample size, and lack of quantitative exposure data. The USEPA has classified benzene as a known human carcinogen by inhalation.

1,3-Butadiene is a colorless gas with a mild gasoline-like odor. Sources of 1,3-butadiene released into the air include motor vehicle exhaust, manufacturing and processing facilities, forest fires or other combustion, and cigarette smoke. Acute exposure to 1,3-butadiene by inhalation in humans results in irritation of the eyes, nasal passages, throat, and lungs. Neurological effects, such as blurred vision, fatigue, headache, and vertigo, have also been reported at very high exposure levels. One epidemiological study reported that chronic exposure to 1,3-butadiene by inhalation resulted in an increase in cardiovascular diseases, such as rheumatic and arteriosclerotic heart diseases. Other human studies have reported effects on blood (ATSDR 2012). No information is available on reproductive or developmental effects of 1,3-butadiene in humans. The USEPA has classified 1,3-butadiene as a probable human carcinogen by inhalation.

Acetaldehyde is mainly used as an intermediate in the synthesis of other chemicals. It is may be formed in the body from the breakdown of ethanol. Acute (short-term) exposure to acetaldehyde results in effects including irritation of the eyes, skin, and respiratory tract. Symptoms of chronic (long-term) intoxication of acetaldehyde resemble those of alcoholism. Acetaldehyde is considered a probable human carcinogen.

DPM/Diesel Exhaust Organic Gases are a complex mixture of hundreds of constituents in either gaseous or particle form. Gaseous components of diesel exhaust include CO_2, oxygen, nitrogen, water vapor, CO, nitrogen compounds, sulfur compounds, and numerous low-molecular-weight hydrocarbons. Among the gaseous hydrocarbon components of diesel exhaust that are individually known to be of toxicological relevance are several carbonyls (e.g., formaldehyde, acetaldehyde, acrolein), benzene, 1,3-butadiene, and polycyclic aromatic hydrocarbons (PAH) and nitro-PAHs. DPM is composed of a center core of elemental carbon and adsorbed organic compounds, as well as small amounts of sulfate, nitrate, metals, and other trace elements. DPM consists primarily of $PM_{2.5}$, including a subgroup with a large number of particles having a diameter less than 0.1 µm. Collectively, these particles have a large surface area, which makes them an excellent medium for adsorbing organic compounds. Also, their small size makes them highly respirable and able to reach the deep lung. Several potentially toxicologically relevant organic compounds, including PAHs, nitro-PAHs, and oxidized PAH derivatives, are on the particles. Diesel exhaust is emitted from on-road mobile sources such as automobiles and trucks and from off-road mobile sources (e.g., diesel locomotives, marine vessels, and construction equipment). DPM is directly emitted from diesel engines (primary PM) and can be formed from the gaseous compounds emitted by diesel engines (secondary PM).

Acute or short-term (e.g., episodic) exposure to diesel exhaust can cause acute irritation (e.g., eye, throat, and bronchial), neurophysiological symptoms (e.g., lightheadedness and nausea), and respiratory symptoms (e.g., cough and phlegm). Evidence also exists for an exacerbation of

allergenic responses to known allergens and asthma-like symptoms (USEPA 2002). Information from the available human studies is inadequate for a definitive evaluation of possible noncancer health effects from chronic exposure to diesel exhaust. However, on the basis of extensive animal evidence, diesel exhaust is judged to pose a chronic respiratory hazard to humans. The USEPA has determined that diesel exhaust is "likely to be carcinogenic to humans by inhalation" and that this hazard applies to environmental exposures (USEPA 2002).

Ethylbenzene is mainly used in the manufacture of styrene. Acute (short-term) exposure to ethylbenzene results in respiratory effects, such as throat irritation and chest constriction, irritation of the eyes, and neurological effects such as dizziness. Chronic (long-term) exposure to ethylbenzene by inhalation has shown conflicting results regarding its effects on the blood. Animal studies have reported effects on the blood, liver, and kidneys from chronic inhalation exposure to ethylbenzene.

Formaldehyde is a colorless gas with a pungent, suffocating odor at room temperature. The major emission sources of formaldehyde appear to be power plants, manufacturing facilities, incinerators, and automobile exhaust. However, most of the formaldehyde in ambient air is a result of secondary formation through photochemical reactions of VOCs and NO_X. The major toxic effects caused by acute formaldehyde exposure by inhalation are eye, nose, and throat irritation and effects on the nasal cavity. Other effects from exposure to high levels of formaldehyde in humans are coughing, wheezing, chest pains, and bronchitis. Chronic exposure to formaldehyde by inhalation in humans has been associated with respiratory symptoms and eye, nose, and throat irritation. The USEPA considers formaldehyde to be a probable human carcinogen.

Naphthalene is used in mothballs and in the production of phthalic anhydride, a chemical compound used in industrial processes that can cause health effects in humans. Acute (short-term) exposure of humans to naphthalene by inhalation, ingestion, and dermal contact is associated with hemolytic anemia, damage to the liver, and neurological damage. Cataracts have also been reported in workers acutely exposed to naphthalene by inhalation and ingestion. Chronic (long-term) exposure of workers and rodents to naphthalene reportedly causes cataracts and damage to the retina. Hemolytic anemia has been reported in infants born to mothers who sniffed and ingested naphthalene (as mothballs) during pregnancy. Available data are inadequate to establish a causal relationship between exposure to naphthalene and cancer in humans. The USEPA has classified naphthalene as a possible human carcinogen.

Polycyclic Organic Matter defines a broad class of compounds that includes PAHs, of which benzo[a]pyrene is a member. Polycyclic organic matter compounds are formed primarily by combustion and are present in the atmosphere in particulate form. Sources of air emissions are diverse and include cigarette smoke, vehicle exhaust, home heating, laying tar, and grilling meat. Cancer is the major concern from exposure to polycyclic organic matter. Epidemiologic studies have reported an increase in lung cancer in humans exposed to coke oven emissions, roofing tar emissions, and cigarette smoke; all of these mixtures contain polycyclic organic matter compounds (USEPA 2016b). Animal studies have reported respiratory tract tumors from inhalation exposure to benzo[a]pyrene and forestomach tumors, leukemia, and lung tumors from oral exposure to benzo[a]pyrene. The USEPA has classified seven PAHs (benzo[a]pyrene, benz[a]anthracene, chrysene, benzo[b]fluoranthene, benzo[k]fluoranthene, dibenz[a,h]anthracene, and indeno[1,2,3-cd]pyrene) as probable human carcinogens.

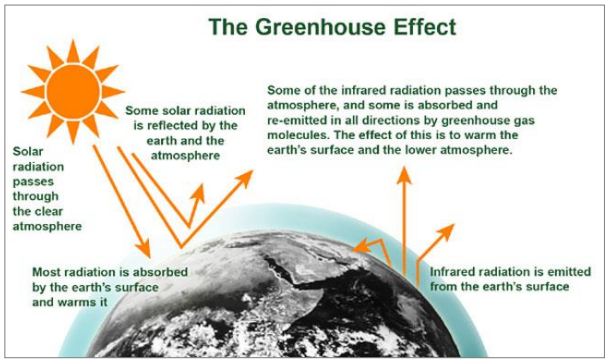
4.3 Valley Fever

Valley fever is not an air pollutant, but is a disease caused by inhaling *Coccidioides immitis* (C. immitis) fungus spores. The spores are found in certain types of soil and become airborne when the soil is disturbed. While C. immitis is not typically found in the Bay Area, the fungus is endemic to the Central Valley (California Department of Public Health 2018). However, the presence of C. immitis in the RSA does not guarantee that construction activities would result in increased incidence of Valley fever. Propagation of C. immitis is dependent on climatic conditions, with the potential for growth and surface exposure highest following early seasonal rains and long dry

spells. C. immitis spores can be released when filaments are disturbed by earthmoving activities, although receptors must be exposed to and inhale the spores to be at increased risk of developing Valley fever. Moreover, exposure to C. immitis does not guarantee that an individual will become ill—approximately 60 percent of people exposed to the fungal spores are asymptomatic and show no signs of an infection (USGS 2000).

4.4 Greenhouse Gases

Gases that trap heat in the atmosphere, or GHGs, are necessary to life, because they keep the planet's surface warmer than it otherwise would be. This is referred to as the *greenhouse effect* (Figure 4-5). As concentrations of GHGs increase, however, the Earth's temperature increases. According to National Oceanic and Atmospheric Administration and National Aeronautics and Space Administration data, the Earth's average surface (land and ocean) temperature has increased by 1.6 degrees Fahrenheit (°F) in the last 100 years (NOAA 2018). According to the USEPA, eight of the top 10 warmest years on record for the United States have occurred since 1998, and 2012 and 2015 were the two warmest years on record. Most of the warming in recent decades is very likely the result of human activities. Other aspects of the climate are also changing, such as rainfall patterns, snow and ice cover, and sea level (USEPA 2016c).



Source: USEPA 2015f *MARCH 2019*

Figure 4-5 The Greenhouse Effect

Some GHGs, such as CO_2, occur naturally and are emitted into the atmosphere through natural processes and human activities. Other GHGs (e.g., fluorinated gases) are created and emitted solely through human activities. GHGs differ in their ability to trap heat. For example, 1 ton of emissions of CO_2 has a different effect than 1 ton of emissions of CH_4. To compare emissions of different GHGs, a weighting factor called Global Warming Potential (GWP) is used. To use a GWP, the heat-trapping ability of 1 metric ton (1,000 kilograms) of CO_2 is taken as the standard, and emissions are expressed in terms of CO_2e. The GWP of CO_2 is 1, the GWP of CH_4 is 25, the GWP of N_2O is 298, and the GWP for SF_6 is 22,800 (CARB 2018a). The following are the principal GHGs that enter the atmosphere because of human activities.

- **CO_2**—CO_2 enters the atmosphere from the burning of fossil fuels (oil, natural gas, and coal), solid waste, trees, and wood products and also as a result of other chemical reactions (e.g., manufacture of cement). CO_2 is also removed from the atmosphere (or "sequestered") when it is absorbed by plants as part of the biological carbon cycle.
- **CH_4**—CH_4 is emitted during the production and transport of coal, natural gas, and oil. CH_4 emissions also result from livestock and other agricultural practices and from the decay of organic waste in municipal solid waste landfills.
- **N_2O**—N_2O is emitted during agricultural and industrial activities, as well as during combustion of fossil fuels and solid waste.
- **Fluorinated gases**—Hydrofluorocarbons, perfluorocarbons, and SF_6 are synthetic, powerful GHGs that are emitted from a variety of industrial processes. Fluorinated gases are sometimes used as substitutes for O_3-depleting substances (e.g., chlorofluorocarbons, hydrochlorofluorocarbons, and halons). These gases are typically emitted in smaller quantities, but, because they are potent GHGs, they are sometimes referred to as high GWP gases.

Because of the global nature of GHG emissions, GHGs are examined for the project on the statewide and regional level. Effects of locally emitted GHGs are felt cumulatively and worldwide.

5 AFFECTED ENVIRONMENT

This chapter summarizes existing air quality and GHG conditions along the project corridor. Air quality is affected by both the rate and location of pollutant emissions and by meteorological conditions that influence movement and dispersal of pollutants. Atmospheric conditions, such as wind speed, wind direction, and air temperature gradients, along with local topography, provide the link between air pollutant emissions and air quality.

5.1 Meteorology and Climate

California is divided into 15 air basins based on geographic features that create distinctive regional climates. The project would cross the SFBAAB, NCCAB, and SJVAB. Accordingly, local meteorological conditions vary greatly along the length of the project because of topography and elevation, as well as proximity to local waterbodies. This section discusses climate and meteorological information associated with the three project air basins.

5.1.1 San Francisco Bay Area Air Basin (Santa Clara Valley Subregion)

Climate within the SFBAAB is divided into 11 climatological subregions. The portion of the project in the SFBAAB crosses the Santa Clara Valley region, which is bounded by San Francisco Bay to the north and by mountains to the east, south, and west. Temperatures are warm on summer days and cool on summer nights, and winter temperatures are mild. At the northern end of the valley, mean maximum temperatures are 79°F to 82°F during the summer and 55°F to 59°F during the winter, and mean minimum temperatures range from 55°F to 59°F in the summer and 39°F to 43°F in the winter. Further inland, where the moderating effect of the bay is not as strong, temperature extremes are greater. For example, in San Martin, located 27 miles south of San Jose International Airport, temperatures can be more than 10°F warmer on summer afternoons and more than 10°F cooler on winter nights.

Winds in the valley are greatly influenced by the terrain, resulting in a prevailing flow that roughly parallels the valley's northwest-southeast axis. A north-northwesterly sea breeze flows through the valley during the afternoon and early evening, and a light south-southeasterly drainage flow occurs during the late evening and early morning. In the summer, the southern end of the valley sometimes becomes a convergence zone, when air flowing from Monterey Bay is channeled northward into the southern end of the valley and meets the prevailing north-northwesterly winds. Wind speeds are greatest in the spring and summer and weakest in the fall and winter. Nighttime and early morning hours frequently have calm winds in all seasons, while summer afternoons and evenings are quite breezy. Strong winds are rare, associated mostly with the occasional winter storm.

The air pollution potential of the Santa Clara Valley is high. High summer temperatures, stable air, and mountains surrounding the valley combine to promote O_3 formation. In addition to the many local sources of pollution, O_3 precursors from San Francisco, San Mateo, and Alameda Counties are carried by prevailing winds to the Santa Clara Valley. The valley tends to channel pollutants to the southeast. On summer days with low-level inversions, O_3 can be recirculated by southerly drainage flows in the late evening and early morning and by prevailing northwesterlies in the afternoon. A similar recirculation pattern occurs in the winter, affecting levels of CO and PM. This movement of the air up and down the valley significantly increases the effects of pollutants (BAAQMD 2017a).

5.1.2 North Central Coast Air Basin

The NCCAB is comprised of Monterey, Santa Cruz, and San Benito Counties. The basin lies along the central coast of California and covers an area of 5,159 square miles. The semi-permanent high-pressure cell in the eastern Pacific, known as the Pacific High, is the basic controlling factor in the climate of the air basin. In the summer, the high-pressure cell is dominant and causes persistent west and northwest winds over the entire California coast. Air descends in the Pacific High, forming a stable temperature inversion of hot air over a cool coastal layer of air. The onshore air currents pass over cool ocean waters to bring fog and relatively cool air into the coastal valleys. The warmer air above acts as a lid to inhibit vertical air movement.

The generally northwest-southeast orientation of mountainous ridges tends to restrict and channel the summer onshore air currents. Surface heating in the interior portion of the Salinas and San Benito Valleys creates a weak low-pressure system that intensifies the onshore air flow during the afternoon and evening.

In the fall, the surface winds become weak, and the marine layer grows shallow, dissipating altogether on some days. The air flow is occasionally reversed in a weak offshore movement, and the relatively stationary air mass is held in place by the Pacific High, which allows pollutants to build up over a period of a few days. It is most often during this season that north or east winds develop and transport pollutants from the Bay Area or Central Valley into the NCCAB.

During the winter, the Pacific High migrates southward and has less influence on the air basin. Air frequently flows in a southeasterly direction out of the Salinas and San Benito Valleys, especially during night and morning hours. Northwest winds are nevertheless still dominant in winter, but easterly flow is more frequent. The general absence of deep, persistent inversions and the occasional storm systems usually result in good air quality for the basin in winter and early spring.

The northern end of the San Benito Valley experiences west winds nearly one-third of the time. The prevailing air flow during the summer months probably originates in the Monterey Bay area and enters the northern end of the San Benito Valley through the air gap through the Gabilan Range occupied by the Pajaro River. In addition, a northwesterly air flow frequently transports pollutants into the San Benito Valley from the Santa Clara Valley (MBUAPCD 2008).

5.1.3 San Joaquin Valley Air Basin

The SJVAB is bounded by the Sierra Nevada to the east, the Coast Ranges to the west, and the Tehachapi Mountains to the south. The SJVAB contains all of San Joaquin, Stanislaus, Merced, Madera, Fresno, Kings, and Tulare Counties, as well as a portion of Kern County.

The area has an inland Mediterranean climate that is characterized by warm, dry summers and cool winters. Summer high temperatures often exceed 100°F, averaging in the low 90s in the northern valley and high 90s in the southern portion.

Although marine air generally flows into the basin from the Delta, the surrounding mountain ranges restrict air movement through and out of the valley. Wind speed and direction influence the dispersion and transportation of pollutants—the more wind flow, the less accumulation.

The vertical dispersion of air pollutants in the SJVAB is limited by the presence of persistent temperature inversion. Because of differences in air density, the air above and below the inversion do not mix. Air pollutants tend to collect under an inversion, leading to higher concentrations of emitted pollutants.

Precipitation and fog tend to reduce pollutant concentrations. O_3 needs sunlight for its formation, and clouds and fog block the required radiation. Precipitation in the San Joaquin Valley decreases from north to south, with approximately 20 inches in the north, 10 inches in the middle, and less than 6 inches in the south (SJVAPCD 2015a).

5.2 Ambient Air Quality

The existing air quality conditions in the project vicinity can be characterized by regional monitoring data. The CARB and various air districts operate air quality monitoring stations throughout California to monitor pollutant concentrations. For the purposes of this analysis, three stations, one in each air basin, were selected to represent conditions along the corridor: San Jose—Jackson Street (SFBAAB), Hollister—Fairview Road (NCCAB), and Merced—South Coffee Avenue (SJVAB).

Table 5-1 shows the results of ambient monitoring at the three stations, where available, for the most recent 3 years of available data (CARB 2018b; USEPA 2018a). Figure 5-1 shows the locations of the monitoring stations relative to the project footprint. Between 2015 and 2017, monitored CO and NO_2 concentrations did not exceed any federal or state standards at any of the three monitoring locations. However, the state and federal standards for O_3 and $PM_{2.5}$ and the

state standard for PM_{10} were exceeded. Using violations of the ambient air quality standards as a proxy for air quality, conditions tend to be poorest in the eastern portion of the project in Merced County, with improving air quality as the project moves westward to the SFBAAB.

5.3 Attainment Status

Local monitoring data (Table 5-1) are used to designate areas as nonattainment, maintenance, attainment, or unclassified for the NAAQS and CAAQS. The four designations are further defined as follows:

- **Nonattainment**—Assigned to areas where monitored pollutant concentrations consistently violate the standard in question.
- **Maintenance**—Assigned to areas where monitored pollutant concentrations exceeded the standard in question in the past, but are no longer in violation of that standard.
- **Attainment**—Assigned to areas where pollutant concentrations meet the standard in question over a designated period of time.
- **Unclassified**—Assigned to areas where data are insufficient to determine whether a pollutant is violating the standard in question.

Table 5-2 shows the attainment status of the project in the SFBAAB, NCCAB, and SJVAB with regard to the NAAQS and CAAQS.

JANUARY 2020

Figure 5-1 Monitoring Station Locations

5.4 Emissions Inventory

An emissions inventory is an accounting of the total emissions from all sources in a particular geographic area over a specified period. Emission inventories are used in air quality planning and can provide a general indication of existing air quality in an area.

5.4.1 Criteria Pollutants

The CARB maintains an annual emission inventory for each county and air basin in the state. The inventories for Santa Clara, San Benito, and Merced Counties are composed of data submitted to the CARB by the local air districts, plus estimates for certain source categories, which are provided by CARB staff.

The 2012 air pollutant inventory data for Santa Clara, San Benito, and Merced Counties is shown in Table 5-3. With the exception of San Benito County, mobile source emissions represent the majority of ROG, NO_X, and CO emissions. In San Benito County, area sources represent the majority of ROG emissions, and mobile source emissions represent the majority of NO_X and CO. Area sources represent the majority of PM_{10} and $PM_{2.5}$ emissions in all three counties.

Table 5-3 Estimated Annual Average Emissions for Santa Clara, San Benito, and Merced Counties (2012 data published in 2017) (tons per day)

Source Category	Santa Clara County						San Benito County						Merced County					
	ROG	CO	NO_X	SO_X	PM_{10}	$PM_{2.5}$	ROG	CO	NO_X	SO_X	PM_{10}	$PM_{2.5}$	ROG	CO	NO_X	SO_X	PM_{10}	$PM_{2.5}$

5.4.2 Statewide Greenhouse Gas Emissions

The CARB maintains a statewide emissions inventory of GHGs. The most recent inventory (2016) is shown in Table 5-4. In 2016, the largest contributor to GHG emissions was the transportation sector (41 percent). This sector includes emissions from on-road vehicles, intrastate aviation, waterborne vessels, and rail operations. The next largest contributor to emissions was the industrial sector (23 percent), followed by electricity generations (in-state and imports) (16 percent).

Table 5-4 California Greenhouse Gas Inventory (2016)

Sector	Emissions (million metric tons CO_2e)	Percent of Inventory
Transportation	174	41%
Industrial	100	23%
Electricity generation (in-state)	43	10%
Electricity generation (imports)	26	6%
Agriculture & forestry	34	8%
Residential	28	7%
Commercial	23	5%
Not specified	1	<1%
Total	429	100%

CO_2e = carbon dioxide equivalent
< = less than

5.5 Sensitive Receptors

Sensitive receptors are people that have an increased sensitivity to air pollution or environmental contaminants. Sensitive receptor locations include schools, parks and playgrounds, day care centers, nursing homes, and hospitals. Residential dwellings are also considered sensitive land uses because people can be exposed to pollutants for extended periods. Recreational areas are considered moderately sensitive to poor air quality because vigorous exercise associated with recreation places a high demand on the human respiratory function.

Analyses performed by the CARB indicate that providing a separation of at least 1,000 feet from diesel sources and high-traffic areas would reduce exposure to air contaminants and decrease asthma symptoms in children (CARB 2005). Sensitive receptors located within 1,000 feet of the San Jose Diridon Station, Downtown Gilroy Station, East Gilroy Station, and East Gilroy MOWF are shown in Table 5-5 and on Figures 5-2 through 5-5. There are no receptors within 1,000 feet of the South Gilroy MOWF. In the RSA, residential land uses are the most common. Other sensitive receptors in the RSA include childcare/schools, elder care facilities, and parks/recreational facilities.

Table 5-5 Sensitive Receptors within 1,000 Feet of the San Jose Diridon and Gilroy Stations and East Gilroy MOWF

Station and Receptor	Distance from Station (feet)[1]	
San Jose Diridon Station	**Alternatives 1, 2, and 3**	**Alternative 4**

6 METHODS FOR EVALUATING EFFECTS

This chapter discusses the methods used to determine the air quality and global climate change effects of the construction and operations of the project. The discussion includes the existing physical conditions that were assumed in the analysis.

Air quality analysts used the year 2015 to represent existing conditions for this analysis (2015 Existing Conditions). The project would be constructed and in operation by 2029, and the full Phase 1 of the statewide HSR system would be operational by 2040. The existing background conditions (e.g., background traffic volumes, trip distribution, and vehicle emissions) of 2015 would change over the 25-year span to full operations in 2040. Changes to the transportation network over the next 25 years will result from funded transportation projects programmed to be constructed by 2040. The buildout of local development plans will affect background traffic volumes. Changes in vehicle emissions over the next 25 years will result from application of updated and more stringent vehicle emissions standards, as well as changing background traffic and VMT. Given these anticipated changes in background conditions over the life of the project from 2015 Existing conditions, the project's air quality operations effects are evaluated against both existing (2015) conditions and background (i.e., No Project) conditions as they are expected to be in 2029 and 2040 (when the full Phase 1 of the statewide HSR system is in operation).

Temporary transportation-related effects, such as those from temporary road closures during construction, are evaluated only against existing conditions. Construction of the project alone could reconfigure the existing roadway network, permanently redirecting existing traffic and causing traffic effects at intersections and road segments that receive the redirected traffic. The 2015 Existing Conditions are particularly helpful for evaluating these effects, and mitigation based on these conditions would be appropriate.

6.1 Definition of Resource Study Area

The RSA is the area in which all environmental investigations specific to air quality and global climate change are conducted to determine the resource characteristics and potential effects of the project. The RSA for air quality and global climate change comprises the state, the regional air districts (SFBAAB, NCCAB, and SJVAB), and the local study areas (areas immediately adjacent to construction activities). Each of these components of the RSA is described in the following subsections.

6.1.1 Statewide

Analysts identified a statewide RSA to evaluate potential changes in GHG/global climate change and air quality from large-scale, nonlocalized factors. Such factors include HSR power requirements, changes in air traffic, and project conformance with the SIP.

6.1.2 Regional

The project would potentially affect regional air pollutant concentrations in the Santa Clara County portion of the SFBAAB, the San Benito County portion of the NCCAB, and the Merced County portion of the SJVAB. Figure 3-1 in Chapter 3 highlights the three air basins in the RSA.

6.1.3 Local

Local RSAs are areas of potential major air emission activities, including areas where construction would occur along the project alignment and near construction staging areas. Local RSAs are generally defined as areas within 1,000 feet of the project footprints or construction staging areas. CARB analyses indicate that providing a separation of 1,000 feet from diesel sources and high-traffic areas substantially reduces DPM concentrations, public exposure, and asthma symptoms in children (CARB 2005). Accordingly, 1,000 feet from the project right-of-way is defined as the local RSA.

6.2 Statewide and Regional Operations Emissions Calculations

The emission burden analysis of a project determines a project's overall effect on air quality levels. The project would affect long-distance, city-to-city travel along freeways and highways throughout the state, as well as long-distance, city-to-city aircraft takeoffs and landings. The HSR system would also affect electrical demand throughout the state. Analysts calculated criteria pollutant and GHG operations emissions for two ridership scenarios: a medium ridership scenario of the Silicon Valley to Central Valley line (from San Francisco to north of Bakersfield) and a high ridership scenario of the same distance. Analysts developed these two scenarios for three different years: 2015 Existing Conditions, 2029 Plus Project conditions (opening), and 2040 Plus Project conditions (Phase 1 of the HSR system horizon 2040). Both scenarios are based on the level of ridership as presented in *Connecting and Transforming California, 2016 Business Plan* (2016 Business Plan) (Authority 2016).[10, 11] These scenarios assume different background conditions. For example, forecast trends in demographics and travel costs can influence ridership for any HSR scenario. The medium scenario was developed using the "most likely" values of all inputs to the HSR ridership forecasting model, while the high scenario used inputs that were set at values that result in ridership at the 75th percentile of the range considered in the ridership risk analysis. The 2016 Business Plan provides additional detail on the travel forecasts and risk analysis. The tables in the effects analysis therefore present two values for operational emissions for each pollutant, corresponding to these two scenarios.

6.2.1 On-Road Vehicles

Analysts evaluated on-road vehicle emissions using average daily VMT estimates and associated average daily speed estimates for each affected county. Analysts estimated emission factors using the CARB emission factor program, EMission FACtors (EMFAC) 2017, which accounts for existing regulations that would reduce emissions, such as the Pavley Clean Car Standards. Parameters were set in the program for each county to reflect conditions within each county and statewide parameters to reflect travel through each county. The analysis was conducted for the following modeling years:

- Existing Year (2015)
- Opening Year (2029)
- Horizon Year (2040)

To determine overall pollutant burdens generated by on-road vehicles, analysts multiplied the estimated VMT by the applicable pollutant's emission factors, which are based on speed, vehicle mix, and analysis year. The difference between emissions with the project and without the project represents the effects of the project.

6.2.2 Trains

The entire HSR system, including the project, would use electric multiple-unit (EMU) trains, with the power distributed through the overhead contact system. Accordingly, the HSR system would not produce direct emissions from combustion of fossil fuels and associated emissions. However, trains traveling at high velocities, such as those associated with the HSR system, create sideways turbulence and rear wake, which resuspend particulates from the surface surrounding

[10] As described in Appendix 3.3-C, Changes to Project Benefits Based on 2018 Business Plan, to the EIR/EIS, the Authority Board adopted the 2018 Business Plan on May 15, 2018. The 2018 Business Plan assumes an opening year of 2033 for Phase 1 and presents different ridership forecasts for 2029 and 2040 than were assumed in this technical report. Under the 2018 Business Plan ridership forecasts, the HSR project would achieve the same benefits described in this section, but they would occur at different times and may be less than presented in Chapter 7, Air Quality Effects Analysis, and Chapter 8, Global Climate Change Effects Analysis. Nonetheless, HSR ultimately affords a more energy-efficient choice for personal travel that would help alleviate highway congestion, provide greater capacity for goods movement, and reduce criteria pollutant and GHG emissions.

[11] As described in the *San Jose to Merced Project Section Transportation Technical Report*, the project would result in a 6.5 percent increase in Caltrain ridership (Authority 2019c). VMT reductions and corresponding emissions benefits from this additional ridership have not been accounted for in this analysis. Accordingly, the long-term benefits reported in this study are likely conservative.

the track, resulting in fugitive dust. Analysts used the USEPA (2006a) method for estimating emissions from wind erosion. They assumed a friction velocity of 0.62 foot per second to resuspend soils and that a HSR train passing at 220 mph could resuspend soil particles out to approximately 10 feet from the train (Watson 1996).

6.2.3 Aircraft

Analysts used the Federal Aviation Administration's Aviation Environmental Design Tool to estimate aircraft emissions. This tool estimates the emissions generated from specified numbers of landing and take-off cycles. Along with emissions from the aircraft, emissions generated from associated ground-maintenance requirements are included. Analysts calculated aircraft emissions by using the fuel consumption factors and emission factors from the CARB's 2000–2018 *Documentation of California's Greenhouse Gas Inventory (13th Edition)* and the accompanying support documentation. The emission factor includes both landing and take-off and cruise operations (formula: aircraft emissions per flight = fuel consumption × emission factor; aircraft emissions = flights removed × aircraft emissions per flight). Analysts calculated average aircraft emissions based on the profile of intrastate aircraft currently servicing the San Francisco to Los Angeles corridor. Analysts estimated the number of air trips removed attributable to the project through the travel demand modeling analysis conducted for the project, based on the ridership estimates presented in the 2016 Business Plan (Authority 2016).

6.2.4 Power Plants

Analysts conservatively estimated the electrical demands caused by propulsion of the trains and the trains at terminal stations and in storage depots and maintenance facilities as part of the project design. Analysts derived average emission factors for each kilowatt-hour (kWh) required from CARB statewide emission inventories of electrical and cogeneration facilities data along with USEPA eGRID2018 (released January 2020) electrical generation data. The energy estimates used in this analysis for the propulsion of the HSR include the use of regenerative brake power.

The HSR system is currently analyzed as if it would be powered by the state's current electric grid. This is a conservative assumption because of the state requirement that an increasing fraction of electricity (100 percent by 2045) generated for the state's power portfolio come from renewable energy sources. As such, the emissions generated for the HSR system are expected to be lower in the future than the emissions estimated for this analysis. Furthermore, under the 2013 Policy Directive POLI-PLAN-03, the Authority has adopted a goal to purchase 100 percent of the HSR system's power from renewable energy sources.

6.3 Local Operations Emissions Calculations

Operation of the project traction power, switching, and paralleling stations would not result in appreciable air pollutants because site visits would be infrequent, and power usage would be limited. Therefore, emissions from these stations were not quantified.

The following sections discuss the methods used to estimate operational emissions from the train stations, maintenance facilities, and additional SF_6 circuit breakers installed during reconductoring activities and evaluate the project's effect on ambient air quality conditions and human health. The HRA focuses on the key localized pollutants of concern, which are CO, PM, and MSATs.

6.3.1 Stations

The project includes an expanded San Jose Diridon Station and either an expanded Downtown Gilroy Station or a new East Gilroy Station.[12] The stations would provide drop-off facilities, an entry plaza, a station house area for ticketing and support services, an indoor station room where passengers wait to access the HSR, and parking facilities. Emissions associated with the operation of the stations would primarily result from area and stationary sources, electricity and

[12] The project section terminates at the Merced Station, which is discussed in the Merced to Fresno Final EIR/EIS and is not included in this analysis.

water consumption, waste generation, emergency generator testing, and vehicle traffic. The methods used to evaluate each of these sources is described in the following subsections.

Since the San Jose Diridon and Downtown Gilroy Stations are existing facilities, emissions were analyzed under both existing and project conditions. The difference between existing and project conditions represents the net effect of the project analyzed. Since the East Gilroy Station would be constructed as part of the project, existing emissions were assumed to be zero.

6.3.1.1 Area Sources

Analysts calculated the criteria pollutant and GHG emissions from area sources using CalEEMod. Emissions were based on the land use data, entered as the size of the station buildings (square feet). The CalEEMod output files and the activity data details used to perform the estimations are summarized in Appendix A.

6.3.1.2 Natural Gas

Analysts calculated criteria pollutant and GHG emissions from natural gas consumption for water and space heating based on the building square footage, existing gas consumption rates, and CalEEMod. The San Jose Diridon Station consumed 1,022 therms of gas in 2016, resulting in a consumption rate of 0.05 therms/square foot/year (McGuire 2017–2018). The Downtown Gilroy Station is currently a platform and does not consume gas. Accordingly, the existing gas rate (0.05 therms/square foot/year) for the San Jose Diridon Station was assumed representative of the future stations at San Jose Diridon and in Gilroy. This assumption is conservative, since the stations would be LEED Platinum certified, which would reduce gas consumption per square foot relative to the existing rate.

6.3.1.3 Indirect Electricity

The San Jose Diridon and Gilroy stations would generate indirect emissions from purchased electricity consumed for facility lighting. It is expected that the power used by HSR stations would be much less than the power used by train operations; however, the indirect emissions from power consumption have been included in the overall emission estimates.

Analysts calculated indirect GHG emissions from purchased electricity consumed by HSR stations based on the building square footage, existing electricity consumption rates, and CalEEMod. The San Jose Diridon and Downtown Gilroy Stations consumed 623,763 and 5,041 kWh of electricity in 2016, resulting in a consumption rate of 28 kWh/square foot/year and 2 kWh/square foot/year, respectively (McGuire 2017–2018). Since the Downtown Gilroy Station is currently a platform, the existing electricity rate (28 kWh/square foot/year) for the San Jose Diridon Station was assumed representative of future project stations at Diridon and in Gilroy. This assumption is conservative, since the project stations would be LEED Platinum certified, which would reduce electricity consumption per square foot relative to the existing stations.

6.3.1.4 Indirect Water and Wastewater

The San Jose Diridon Station, Downtown Gilroy Station, and East Gilroy Station would generate indirect GHG emissions from purchased water consumed for facility restrooms, drinking fountains, landscaping, and other miscellaneous uses. Analysts calculated indirect GHG emissions from purchased water consumed by the HSR stations based on the building square footage, existing water consumption rates, and CalEEMod. The San Jose Diridon and Downtown Gilroy Stations consumed 1.9 million and 130,000 gallons of water per year, resulting in a consumption rate of 89 gallons/square foot/year and 49 gallons/square foot/year, respectively (McGuire 2017–2018). Since the Downtown Gilroy Station is currently a platform, the existing water rate (89 gallons/square foot/year) for the San Jose Diridon Station was assumed representative of the future project stations at San Jose Diridon and in Gilroy. This assumption is conservative, since the project stations would be LEED Platinum certified, which would reduce water consumption per square foot relative to the existing stations.

6.3.1.5 Indirect Solid Waste

The San Jose Diridon and Gilroy stations would generate indirect GHG emissions from solid waste disposal. Waste generation at the existing San Jose Diridon and Gilroy stations was not available. Accordingly, analysts calculated indirect GHGs from solid waste generation using CalEEMod defaults.

6.3.1.6 Emergency Generators

The San Jose Diridon and Gilroy stations would have emergency generators that would be used in the event of a power outage. Analysts assumed that the emergency generators would be Tier 4, 800-kilowatt generators. Usage of each of the proposed emergency generators would occur for up to 50 hours per year for periodic testing, consistent with CARB's Airborne Toxic Control Measure for Stationary Compression Ignition Engines and Section 330.3 of BAAQMD Regulation 9, Rule 8. Analysts modeled emissions using CalEEMod.

6.3.1.7 Vehicle Traffic

Passengers

Mobile source emissions would occur from passenger commutes. Passengers would be expected to arrive at the San Jose Diridon and Gilroy stations by car, shuttle, and bus/rail.[13] The numbers of daily passengers visiting the San Jose Diridon and Gilroy stations are shown in Table 6-1. As a conservative estimate, passenger traffic was expected to occur 7 days per week.

Analysts estimated vehicular exhaust emissions from passengers arriving by car using CalEEMod assuming a mix of light-duty automobiles and light-duty trucks. Connecting bus/shuttle service would primarily be provided by the Santa Clara Valley Transportation Authority (VTA). Connecting rail service includes Caltrain, Bay Area Rapid Transit, and VTA light rail. Connecting transit service to the passenger rail terminals is not part of the project. The Authority assumes that bus service levels are constant into the future given that no operator has a funding plan to deliver more service. Routing buses to the new East Gilroy Station would be the responsibility of VTA as part of their long-range expansion plans, which would outline anticipated service and vehicle needs commensurate with the expected East Gilroy demand. Accordingly, mass emissions generated by connecting transit are not included in the air quality or GHG assessment for the project.

Employees

Analysts calculated emissions from employee traffic using CalEEMod based on weighted average vehicle emission factors for light-duty automobiles and light-duty trucks. As a conservative estimate, employee traffic was expected to occur 7 days per week. It was assumed that each employee would make one round trip per day. There would be a total of 36 daily employee round trips at the San Jose Diridon Station and 29 daily employee roundtrips at the Downtown Gilroy or East Gilroy Station (Burton 2017c).

6.3.1.8 Adjustment for the Safe Vehicles Rule

Analysts adjusted the predicted passenger and employee vehicle emissions to reflect the impact of the SAFE Vehicles Rule, as per CARB (2019, 2020) guidance. As discussed in Section 3.1.4, Federal Greenhouse Gas Regulations and Guidance, the SAFE Vehicles Rule only impacts fuel economy and associated emissions from light-duty gasoline vehicles. However, the adjustment factors were conservatively applied to the entire CalEEMod output for on-road mobile, which includes emissions contributions from gasoline and diesel-powered vehicles.

6.3.2 Maintenance Facilities

Two maintenance facilities would be required for the project. A MOWF would be constructed either south of Gilroy (Alternatives 1, 2, and 4) or east of Gilroy (Alternative 3), and a MOWS

[13] Biking and walking trips have been excluded from the table and analysis since there would be no emissions.

would be built near Turner Island Road (Alternatives 1, 2, 3, and 4). Activities performed at the MOWF would consist of planning maintenance work, storing and dispatching rail mounted equipment, inspecting and maintaining rail mounted equipment, and transporting right-of-way equipment. The purpose of the MOWS is to support the MOWF activities by providing temporary storage of materials and other resources.

Table 6-1 Daily Passengers at HSR Stations

Mode of Access	San Jose Diridon	Downtown Gilroy	East Gilroy
By car			
Existing			
Without HSR	2,400	190	0
With HSR	3,860	2,470	2,470
Future without HSR			
2029	3,380	270	0
2040	4,280	340	0
Future with HSR			
2029	4,840	3,300	4,080
2040	9,940	7,100	8,000
By shuttle (with and without HSR)[1]			
2029	1,800	940	1,500[2]
2040	4,300	2,000	3,800[2]
By bus/rail (with and without HSR)[1]			
2029	5,800	1,100	260[2]
2040	12,300	2,300	560[2]

Sources: Burton 2017a, 2017b, 2018
HSR = high-speed rail
[1] The with HSR conditions are the same as the No Project condition. The Authority assumes that bus service levels are constant into the future given that no operator has a funding plan to deliver more service.
[2] While bus service levels are assumed to be the same under with and without project conditions, the East Gilroy Station would be an entirely new transit stop with HSR conditions. Localized emissions and potential health risks from exposure to diesel-exhaust under this specific project-induced change are assessed in Section 7.3.1, Station Sites and Maintenance Facilities.

Analysts used CalEEMod to estimate building operation emissions, assuming default conditions for the *general light industrial* land use category (Appendix A). It was assumed that there would be an average of 20 truck deliveries to the MOWF and MOWS per day and that the trucks would travel 120 miles round trip. Truck deliveries would include supplies of materials and chemicals, as well as remove refuse from the site. There would be a total of 450 daily employee trips at the MOWF (Burton 2017c).[14] One emergency generator was assumed to operate 50 hours per year at each facility. The emission outputs are provided in Appendix A.

Emissions from maintenance equipment, vehicle, and rail movement at the MOWF were estimated using a combination of emission factors and methodologies from CalEEMod, EMFAC2017, and the USEPA (2009). Daily and annual equipment, vehicle, and locomotive

[14] Analysts adjusted the predicted employee vehicle emissions to reflect the impact of the SAFE Vehicles Rule, as per CARB (2019, 2020) guidance. The MOWS would require six employees per day, all of whom would arrive by rail (Burton 2017c).

operating activity were obtained from the Authority (Newson 2018). Rail mounted equipment would include track treatment machinery, right-of-way inspection/maintenance machinery, and hi-rail specialist equipment. Vehicles would primarily include hi-rail trucks, SUVs, and section trucks. Locomotives would be used to support maintenance, grinding, milling, inspection, welding, and other activities.

Prior to operation in 2029, new equipment will be purchased for the MOWF that, at a minimum, conforms to Tier 4 emission standards. EPA and CARB phased-in Tier 4 emission standards over the period of 2008 to 2015. Accordingly, all newly purchased or remanufactured off-road equipment and locomotives after 2015 must meet Tier 4 emission standards. It is possible more stringent emission standards will be introduced and effective by the time new equipment is purchased for the MOWF. However, because Tier 4 is the standard currently required for new and remanufactured equipment, this analysis conservatively assumes all off-road equipment and locomotives operating at the MOWF meet Tier 4 emissions standards. If more stringent standards are adopted prior to new equipment purchase, emissions and health risks would be lower than presented in this analysis. The emission calculations are provided in Appendix A.

6.3.3 Sulfur Hexafluoride Circuit Breakers

Operations and maintenance activities required for the reconductored Spring to Llagas and Green Valley to Llagas power lines would not change from those currently required for the existing system; thus, no additional operations-related criteria pollutants would occur. However, the project would require the installation of electrical equipment, including up to 12 power circuit breakers with SF_6-gas-insulated switchgear. Potential SF_6 emissions from the additional breakers were estimated based on the mass of each breaker (230 pounds) and an assumed 0.5 percent by mass annual leak rate, per PG&E standard specifications.

6.3.4 Microscale Carbon Monoxide Hot Spot Analysis

Traffic around the San Jose Diridon and Gilroy stations and affected by grade crossings (Alternative 4 only) may contribute to localized increases in CO, known as CO “hot spots”. The BAAQMD has adopted screening criteria that provide a conservative indication of whether project-generated traffic would cause a potential CO hot spot. The air district establishes that if the screening criteria are not met, a quantitative analysis through site-specific dispersion modeling of project-related CO concentrations would not be necessary, and the project would not cause localized exceedances of CO CAAQS. BAAQMD’s screening criteria were developed based on local modeling and provide a conservative estimate for the maximum number of vehicles that can be added to an intersection without an exceedance of the CO CAAQS. BAAQMD CO screening criteria are as follows:

1. Project traffic would not increase traffic volumes at affected intersections to more than 44,000 vehicles per hour.
2. Project traffic would not increase traffic volumes at affected intersections to more than 24,000 vehicles per hour where vertical and/or horizontal mixing is substantially limited (e.g., tunnel, parking garage, bridge underpass, natural or urban street canyon, below-grade roadway).
3. The project is consistent with an applicable CMP established by the county congestion management agency for designated roads or highways, RTP, and local congestion management agency plans.

Traffic data provided by Fehr & Peers (Burton 2017d) indicate that no intersections in the local RSA would exceed 24,000 vehicles per hour. The intersection analysis included all intersections affected by station traffic and near grade crossings. Up to 20 intersections, depending on the alternative, would violate the established LOS standard in the applicable CMP under 2040 Plus Project conditions. Analysts performed a microscale CO hot-spot analysis at five of these locations near stations and one at-grade crossing (Alternative 4) to verify that project traffic would not cause or contribute to a violation of the CO CAAQS. The potential for CO hot spots was evaluated using the Caltrans Institute of Transportation Studies *Transportation Project-Level Carbon Monoxide Protocol* (CO Protocol) (Garza et al. 1997). The CO Protocol details a step-by-

step procedure to determine whether project-related CO concentrations have a potential to generate new air quality violations, worsen existing violations, or delay attainment of CAAQS or NAAQS for CO. Additional details of the modeling are described in the following subsections.

6.3.4.1 Intersection Selection

Analysts ranked the 20 intersections that would violate the established CMP LOS standards by their total peak-hour traffic volumes and anticipated delay. The five intersections with the highest station traffic volumes and worst congestion were selected for CO modeling. Analyzing these intersections provides a worst-case assessment of potential CO effects because CO concentrations at all other intersections would be lower than those estimated for the selected intersections. The following intersections were selected for the analysis:

- The Alameda (SR 82)/Taylor Street-Naglee Avenue
- Autumn Street (SR 82)/West Santa Clara Street (SR 82)
- Coleman Avenue/I-880 Northbound Ramps
- Monterey Road (SR 82)/Blossom Hill Road Westbound Ramps (SR 82/County Route G10)
- US 101 Southbound Ramps/Blossom Hill Road

In addition to these locations, the intersection of Monterey Road and Skyway Drive was analyzed under Alternative 4. The traffic analysis indicates that this intersection would have the highest traffic volumes and worst congestion of the locations analyzed with at-grade crossings (Burton 2017d).

6.3.4.2 Receptor Locations

Receptors for the intersection analyses were identified in accordance with CO Protocol (Garza et al. 1997). All receptors were located at a height of 6 feet. Receptors for the intersection analysis were located 10 feet from the roadway so they were not within the mixing zone of the travel lanes and were spaced at 0, 82, and 164 feet from the intersection for both the 1-hour and 8-hour analyses (Garza et al. 1997). Analysts assumed that the public could access these locations whether or not sidewalks exist at the receptor location.

6.3.4.3 Emission Model

Analysts estimated vehicular emissions using EMFAC2017, which is a mobile source emission estimate program that provides current and future estimates of emissions from highway motor vehicles. Consistent with the traffic analysis and the anticipated design year of the project, CO emission factors are based on 2029 and 2040 vehicle mixes for projected conditions in Santa Clara County. The CARB designed EMFAC2017 to address a wide variety of air pollution modeling needs, and the program incorporates fleet-specific emission rates, realistic driving patterns, separation of start and running emissions, correction factors for engine deterioration, and annual fleet compositions.

6.3.4.4 Dispersion Model

Mobile source dispersion models are the basic analytical tools used to estimate CO concentrations expected under given traffic, roadway geometry, and meteorological conditions. The mathematical expressions and formulations that constitute the various models attempt to describe as closely as possible a complex physical phenomenon. Analysts used Caltrans' CALINE4 dispersion model to estimate pollutant concentrations near roadway intersections.

CALINE4 is a Gaussian model recommended in the Caltrans CO Protocol. Gaussian models assume that the dispersion of pollutants downwind of a pollution source follow a normal distribution around the center of the pollution source. The model is described in *CALINE4 – A Dispersion Model for Predicting Air Pollutant Concentration near Roadways, FHWA/CA/TL-84/15*. The analysis of roadway CO effects followed the CO Protocol (Garza et al. 1997). The CALINE4 output files are provided in Appendix B.

6.3.4.5 Meteorological Conditions

The transport and concentration of pollutants emitted from motor vehicles are influenced by three principal meteorological factors: wind direction, wind speed, and the temperature profile of the atmosphere. Analysts chose the values for these parameters to maximize pollutant concentrations at each prediction site (i.e., to establish a conservative worst-case situation).

- **Wind direction**—Maximum CO concentrations are normally found when the wind is assumed to blow approximately parallel to a single roadway adjacent to the receptor location. However, at complex intersections, it is difficult to predict which wind angle would result in maximum concentrations. Therefore, at each receptor location, the approximate wind angle that would result in maximum pollutant concentrations was used in the analysis. All wind angles from 0° to 360° were considered.
- **Wind speed**—CO concentrations are greatest at low wind speeds. A conservative wind speed of 1 mph was used to predict CO concentrations during peak traffic periods.
- **Temperature and profile of the atmosphere**—Analysts chose an ambient temperature based on the CO Protocol (Garza et al. 1997) recommendation for the local RSA, a mixing height (the height in the atmosphere to which pollutants rise) of 1,000 feet. Neutral atmospheric stability (stability class G) conditions was used in estimating microscale CO concentrations. Winter low temperatures of 41°F were assumed based on the average temperature in December over an approximately 30-year period (based on Western Regional Climate Center data accessed in February 2017). The stability class G was chosen, as recommended in Table B.11 of the CO Protocol.

Analysts based the selection of these meteorological parameters on recommendations from the CO Protocol (Garza et al. 1997) and the USEPA (1992) guidelines. These data were found to be the most representative of the conditions in the RSA.

6.3.4.6 Persistence Factor

Analysts obtained peak 8-hour concentrations of CO by multiplying the highest peak-hour CO estimates by a persistence factor. The persistence factor accounts for the following characteristics:

- Over an 8-hour period (as distinct from a single hour), vehicle volumes fluctuate downward from the peak hour.
- Vehicle speeds may vary over an 8-hour period compared to a single hour.
- Meteorological conditions, including wind speed and wind direction, vary compared with the conservative assumptions used for the single hour.
- Analysts used a persistence factor of 0.7 in this analysis, which is recommended in the CO Protocol (Garza et al. 1997).

6.3.4.7 Background Concentrations

Analysts added background CO concentrations based on local air quality monitoring data (2015 to 2017) to project-level results to account for sources of CO not included in the modeling. Background concentrations for 2029 and 2040 No Project conditions were assumed to be the same as those for the current year. Actual 1- and 8-hour background concentrations in future years would likely be lower than concentrations used in the CO modeling analysis because the CO emissions and concentrations are decreasing because of continuing improvements in engine technology and the retirement of older, higher-emitting vehicles.

6.3.4.8 Traffic Information

Analysts derived traffic data for the air quality analysis from traffic counts and other information developed as part of an overall traffic analysis for the project (Burton 2017d). The microscale CO analysis was performed based on data from this analysis for the afternoon-evening (p.m.) peak

traffic period. This is the period when maximum traffic volumes occur on local streets and the greatest traffic and air quality effects of the project are expected.

6.3.4.9 Adjustment for the Safe Vehicles Rule

Analysts adjusted the predicted CO concentrations to reflect the impact of the SAFE Vehicles Rule, as per CARB (2019) guidance. As discussed in Section 3.1.4, Federal Greenhouse Gas Regulations and Guidance, the SAFE Vehicles Rule only impacts fuel economy and associated emissions from light-duty gasoline vehicles. However, the adjustment factors were conservatively applied to the entire modeled CO concentration, which includes emissions contributions from gasoline and diesel-powered vehicles.

6.3.5 Particulate Matter (PM_{10} and $PM_{2.5}$) Hot-Spot Analysis

PM hot spots may be created by localized increases in vehicle or rail traffic, particularly when that traffic consists of a significant number of diesel-powered vehicles. Redistributing or moving vehicle or rail traffic would also increase PM concentrations at certain locations and result in corresponding decreases in other locations. This section discusses methods for evaluating potential PM hot spots from changes in on-road vehicle and freight rail traffic.

6.3.5.1 On-Road Vehicles

Although the project is not subject to transportation conformity, portions of the local RSA are classified as nonattainment or maintenance for the federal PM_{10} or $PM_{2.5}$ standards. Consequently, analysts conducted a hot-spot analysis following the USEPA's 2015 *Transportation Conformity Guidance for Quantitative Hot-Spot Analyses in $PM_{2.5}$ and PM_{10} Nonattainment and Maintenance Areas* (USEPA 2015e). The analysis focused on potential air quality concerns under NEPA from the project's effects on roads and followed the recommended practice in the USEPA's Final Rule regarding the localized or hot-spot analysis of $PM_{2.5}$ and PM_{10} (40 C.F.R. Part 93, issued March 10, 2006)

The USEPA specifies in 40 C.F.R. Section 93.123(b)(1) that only "projects of air quality concern" are required to undergo a $PM_{2.5}$ and PM_{10} hot-spot analysis. The USEPA defines projects of air quality concern as certain highway and transit projects that involve significant levels of diesel traffic, or any other project identified by the $PM_{2.5}$ SIP as a localized air quality concern. Table 6-2 shows project types that require a $PM_{2.5}$ or PM_{10} hot-spot analysis, as defined by Section 93.123(b)(1) of the Conformity Rule.

Table 6-2 Projects of Air Quality Concerns as Defined by Section 93.123(b)(1) of the Transportation Conformity Rule

Section 93.123(b)(1) Subsection	Type of Project
i	New highway projects that have a significant number of diesel vehicles and expanded highway projects that have a significant increase in the number of diesel vehicles.
ii	Projects affecting intersections that are at LOS D, E, or F with a significant number of diesel vehicles, or those that will change to LOS D, E, or F because of increased traffic volumes from a significant number of diesel vehicles related to the project.
iii	New bus and rail terminals and transfer points that have a significant number of diesel vehicles congregating at a single location.
iv	Expanded bus and rail terminals and transfer points that significantly increase the number of diesel vehicles congregating at a single location.

Section 93.123(b)(1) Subsection	Type of Project
v	Projects in or affecting locations, areas, or categories of sites that are identified in the $PM_{2.5}$ or PM_{10} applicable implementation plan or implementation plan submission, as appropriate, as sites of violation or possible violation.

Source: 40 C.F.R. Section 93.123(b)(1)
LOS = level-of-service
$PM_{2.5}$ = particulate matter 2.5 microns or less in diameter
PM_{10} = particulate matter 10 microns or less in diameter

The following projects are examples of what would be classified as projects of air quality concern, as defined by 40 C.F.R. Section 93.123(b)(1).

- A project on a new highway or expressway that serves a significant volume of diesel truck traffic, such as facilities with greater than 125,000 annual average daily traffic where 8 percent or more of such annual average daily traffic is diesel truck traffic.
- New exit ramps and other highway facility improvements to connect a highway or expressway to a major freight, bus, or intermodal terminal.
- Expansion of an existing highway or other facility that affects a congested intersection (operating at LOS D, E, or F) that has a significant increase in the number of diesel trucks.
- Similar highway projects that involve a significant increase in the number of diesel transit buses or diesel trucks.
- A major new bus or intermodal terminal that is considered to be a "regionally significant project" under 40 C.F.R. Section 93.101.[15]
- An existing bus or intermodal terminal that has a large vehicle fleet where the number of diesel buses increases by 50 percent or more, as measured by bus arrivals.

6.3.5.2 Freight Rail

Neither UPRR service nor associated emissions from locomotive operation would be affected by the proposed freight relocation, relative to existing conditions. While the source of PM emissions would shift commensurate with the lateral track shift, the amount of emissions, and therefore the potential for the project to result in new or worsened PM hot spots, would not change. Accordingly, analysts did not conduct a PM hot-spot analysis for the relocated freight service because there would be no effect under the USEPA definition of projects of air quality concern. Potential changes in receptor exposure to DPM and $PM_{2.5}$ are analyzed further, as described in Section 6.3.7.1, Freight Relocation.

6.3.6 Mobile Source Air Toxics Analysis

On February 3, 2006, the FHWA released Interim Guidance on Air Toxic Analysis in NEPA Documents. This guidance was superseded on September 30, 2009, by the FHWA's Interim Guidance Update on Mobile Source Air Toxic Analysis in NEPA Documents (Interim Guidance), and was most recently updated on October 18, 2016 (FHWA 2016). The updated Interim Guidance advises on when and how to analyze MSATs in the NEPA process for highway projects. This guidance is interim because MSAT science is still evolving, but is used in the

[15] 40 C.F.R. Section 93.101 defines a "regionally significant project" as "a transportation project (other than an exempt project) that is on a facility which serves regional transportation needs (such as access to and from the area outside of the region, major activity centers in the region, major planned developments such as new retail malls, sports complexes, etc., or transportation terminals as well as most terminals themselves) and would normally be included in the modeling of a metropolitan area's transportation network, including at a minimum all principal arterial highways and all fixed guideway transit facilities that offer an alternative to regional highway travel."

analysis of potential effects based on guidance provided by the Authority. As the science progresses, the FHWA is expected to update the guidance.

A qualitative analysis provides a basis for identifying and comparing the potential differences in MSAT emissions, if any, among the project alternatives. The Interim Guidance groups projects into the following tier categories:

- **Tier 1**—No analysis for projects without any potential for meaningful MSAT effects
- **Tier 2**—Qualitative analysis for projects with low potential MSAT effects
- **Tier 3**—Quantitative analysis to differentiate alternatives for projects with higher potential MSAT effects

The project would reduce regional VMT, traffic congestion, and aircraft operations, resulting in a reduction in MSAT emissions. The level of effects from regional MSAT emissions therefore corresponds to FHWA's Tier 1. Accordingly, analysts noted changes to regional MSAT emissions but did not perform quantitative or qualitative analyses of the project alternatives, consistent with FHWA's Interim Guidance.

Changes in vehicle activity could result in localized MSAT increases. The potential level of effects from these circumstances corresponds to FHWA's Tier 2. Accordingly, analysts used a qualitative analysis to provide a basis for identifying and comparing the potential differences in local MSAT emissions, if any, among the project alternatives. The qualitative assessment is derived, in part, from *A Methodology for Evaluating Mobile Source Air Toxic Emissions among Transportation Project Alternatives* (FHWA 2011).

6.3.7 Operations Health Risk Assessment

6.3.7.1 Freight Relocation

Construction of the project would reposition existing UPRR tracks. Redistributing or moving existing freight traffic would increase TAC concentrations at certain receptor locations and would result in corresponding decreases at other locations. Because diesel-related exhaust, specifically DPM, is considered a carcinogenic TAC by the CARB, a human HRA was conducted to assess the risk (i.e., cancer risks and chronic acute risks) associated with changes in operational freight activity. Table 6-3 shows the relocated track segments included in the analysis and summarizes the distances to the nearest receptor under existing conditions and with the track relocation.

Table 6-3 Relocated Freight Tracks and Distances to Nearest Sensitive Receptors

General Location	Description of Maximum Track Shift Relative to Receptor Locations	Distance to Nearest Receptor			Reduction in Distance
		Receptor #	Existing Alignment	Relocated Alignment	
Repositions under Alternatives 1 through 3					
Near Monterey Road and Blanchard Road	The relocated track would be approximately 14 feet closer to an existing residential receptor near Monterey Road and Blanchard Road. After this point, the tracks would be shifted up to about 80 feet to the south of the existing line, but there are no receptors within 1,000 feet of the track.	1	61 feet	47 feet	14 feet
Between Monterey Road and Crowner Avenue	The relocated track would require demolition of structures between the existing tracks and Crowner Ave. Receptors west of Crowner Ave would be approximately 110 feet closer to the relocated track than the existing track.	2	230 feet	120 feet	110 feet
Near Monterey Road and California Avenue	The relocated track would be approximately 69 feet closer to an existing residential receptor.	3	164 feet	95 feet	69 feet
Near Monterey Road and Ronan Avenue	The relocated track would be approximately 61 feet closer to New Hope Community Church.	4	359 feet	298 feet	61 feet
Near Monterey Road and Leavesley Road	The relocated track would be approximately 213 feet closer to homes along Swanston Lane.	5	621 feet	408 feet	213 feet
Near Monterey Road and 1st Street	The relocated track would be approximately 129 feet closer to a football field.	6	193 feet	64 feet	129 feet
Near Monterey Road and W 10th Street	The VTA yard would be relocated approximately 2,500 feet south of its existing location. The nearest receptor to the relocated yard is approximately 309 feet to the west under Alternatives 1 and 2 (this receptor is approximately 398 feet from the existing track).	7	398 feet	309 feet	89 feet
Repositions under Alternative 3 Only					
Near Pacheco Court and Frazier Lake Road	Under Alternative 3, the track south of Church Avenue would be relocated eastward to join with the MOWF. The receptor furthest from the existing track and closest to the relocated track (i.e., the receptor with the greatest potential change in health risk) is off Pacheco Court.	8	9,749 feet	56 feet	9,693 feet
Repositions under Alternative 4 Only					
Near Chestnut Street and Asbury St	The relocated track would shift eastward between Emory St and Diridon Station. Most of this area is dominated by commercial uses. The greatest shift near existing receptors is approximately 20 feet.	9	290 feet	270 feet	20 feet

General Location	Description of Maximum Track Shift Relative to Receptor Locations	Distance to Nearest Receptor			Reduction in Distance
		Receptor #	Existing Alignment	Relocated Alignment	
Near Harrison Street and Fuller Ave	The relocated track would swing further south between I-280 and SR 87. The greatest shift near existing receptors is approximately 29 feet.	10	83 feet	54 feet	29 feet
Near Cross Way and Northern Road	Additional storage tracks would be added to Michael Yard (between W Alma and Almaden Rd). The new tracks would be approximately 16 feet closer to existing single-family homes.	11	322 feet	306 feet	16 feet
End of Promme Court	The tracks would be shifted east from just south of Almaden Expressway to south of Communications Hill. The greatest shift near existing receptors is approximately 7 feet.	12	81 feet	74 feet	7 feet
Near Prindiville Road and Urshan Way	The tracks would be shifted east between Monterey Road and Tulare Hill. There are residential subdivisions along this alignment. The greatest shift near existing receptors is approximately 10 feet.	13	160 feet	150 feet	10 feet
Near Madrone Ave and Dougherty Ave	South of Blanchard Rd until Bailey Rd, there would be a new UPRR siding track east of the existing tracks. The track would continue south shifted to the east until just south of the Gilroy Station. There are receptors throughout this area; the greatest shift would be approximately 65 feet closer to an apartment complex.	14	1025 feet	960 feet	65 feet
Near Butterfield Blvd and E Dunne Ave	The Redwood lumber industry spur would be realigned on the west side of the alignment. The tracks would move approximately 10 feet closer to existing single-family homes.	15	70 feet	60 feet	10 feet
End of Sister City Way	Additional storage tracks would be added to the west side of the alignment just south of Gilroy Station. The new tracks would be 90 feet closer to existing single-family homes.	16	395 feet	305 feet	90 feet
Near Garlic Farms Dr and Trave Park Cir	The tracks would be shifted southwest just east of US 101 and would be approximately 100 feet closer to an existing mobile home community.	17	475 feet	375 feet	100 feet
Near Bolsa Rd	The UPRR Hollister track would be realigned southwest of Carnadero Ave. to provide freight access to the MOWF. The track would be approximately 545 feet closer to an existing single-family home.	18	1,320 feet	775 feet	545 feet
Near West Julian St and North Montgomery St	The tracks would be shifted northeast and would be approximately 37 feet closer to existing single-family homes off West Julian Street	19	222 feet	185 feet	37 feet

Source: McGuire 2017–2018
VTA = Santa Clara Valley Transportation Authority

SR = State Route
UPRR = Union Pacific Railroad
US = U.S. Highway

The BAAQMD maintains an inventory of health risks associated with stationary sources, roadway, and rail sources within the SFBAAB (Winkel 2018). The inventory was used to characterize the net effect of health risks associated with moving operations-related diesel engine locomotive emissions closer to existing sensitive receptors located near the new and shifted tracks. BAAQMD's inventory is based on rail volumes and emission factors in 2015. There were approximately four freight trips per day between Gilroy and San Jose Diridon in 2015, and freight volumes are anticipated to grow by 4 percent per annum (PCJPB 2015). Conversely, locomotive emission factors are anticipated to decrease as a function of time because of natural fleet turnover. Emission rates specific to UPRR are not available; however, data from the USEPA (2009) indicate that national average freight emissions of PM_{10} are expected to decline by 41 percent between 2015 and 2022, which is the first year full operation on the relocated lines could occur. Analysts used the annual growth in freight and decrease in PM_{10} emissions to adjust the 2015 risks from BAAQMD's inventory to be representative of conditions in 2022.

6.3.7.2 Diesel Buses

The San Jose Diridon and Gilroy stations would be served by diesel-powered buses, which generate TACs at idle while loading and unloading passengers. Improved bus service to the passenger rail terminals is not part of the project. The Authority assumes that bus service levels are constant into the future given that no operator has a funding plan to deliver more service. Buses operated by VTA are a mix of diesel- and diesel-electric-powered. The agency also has five fully electric buses. Pursuant to the Innovative Clean Transit Regulation, VTA's bus fleet will be comprised of only zero-emission vehicles by 2040. Thus, diesel bus emissions associated with the San Jose Diridon and Gilroy Stations are expected to decline relative to existing emissions levels as electric buses are integrated into the fleets over time.

While bus service levels are assumed to be the same with and without the project, the East Gilroy Station would be an entirely new transit stop with HSR. Analysts evaluated potential health risks from exposure to diesel exhaust under this specific project-induced change based on the anticipated number of daily shuttle and bus trips at the station (Burton 2019). Analysts assumed each bus would idle for a maximum of 5 minutes for passenger loading/unloading.[16] Analysts quantified running exhaust emissions along the 1,000-foot approach and departure route and station idling emissions using EMFAC2017. Analysts conservatively assumed all buses in 2029 would be diesel powered (VTA operates a mix of diesel-, diesel-electric, and fully-electric buses). Analysts quantified health risks using the USEPA's AERMOD dispersion model and EMFAC emissions results.

6.3.7.3 Emergency Generators

The San Jose Diridon and Gilroy stations and the MOWS and MOWF would have emergency generators that would be used in the event of a power outage. Section 2.3.1 from the BAAQMD's Permit Handbook indicates that "typically any stationary diesel engines over 50 horsepower will require a risk screening analysis" (BAAQMD 2016). Explicitly, BAAQMD Regulation 2, Rule 5, Section 302 specifies that an Authority to Construct permit or Permit to Operate from the BAAQMD will be denied if any new and modified sources of TAC (which includes generators) in excess of 50 horsepower would result in health risks in excess of 10.0 in one million or a hazard index of 1.0. BAAQMD Regulation 2, Rule 5, Section 302 is cited as the evidence in support of BAAQMD's health risk thresholds.

The generators associated with the project would be subject to the permitting requirements specified in BAAQMD Regulation 2, Rule 5, Section 302. Based on these permitting requirements, the emergency generators would not receive a permit from the BAAQMD and would not be allowed to operate at the stations or maintenance facilities if they would result in cancer or acute hazard effects in excess of the BAAQMD's health risk thresholds of significance. However, Regulation 2, Rule 5 does not address $PM_{2.5}$ concentrations or permit

[16] Pursuant to California's Commercial Vehicle Idling Regulation, idling for more than 5 minutes at a single location is prohibited for vehicles of 10,000 pounds or heavier.

restrictions for facilities with emissions more than the BAAQMD's threshold of 0.3 micrograms per cubic meter ($\mu g/m^3$). Accordingly, $PM_{2.5}$ exhaust concentrations from emergency generator testing were estimated using the USEPA's AERMOD dispersion model and emission data from CalEEMod.

6.3.7.4 Maintenance of Way Facility Maintenance Activities

The MOWF would use diesel-powered off-road equipment, vehicles, and locomotives to support maintenance and repair activities. Cancer and noncancer health risks, as well as $PM_{2.5}$ concentrations, were modeled using the USEPA's AERMOD dispersion model. The analysis was conducted using the same general method and guidance as the construction HRA. Refer to Section 6.4.9, Construction Health Risk Assessment, for additional detail.

6.4 Construction Emissions Calculations

Analysts assessed and quantified air quality effects associated with construction of the project using industry standard and accepted software tools, techniques, and emission factors. This section provides a summary of the methods. Appendix C provides a full list of assumptions.

6.4.1 Construction Activities

Analysts quantitatively estimated construction emissions for the earthwork and major civil construction activity during construction of the following components of the project:

- Viaduct
- Embankment
- At grade
- Trench
- Tunnel
- Cut and fill

Construction activities associated with each component include demolition, excavation, utilities, roadwork, concrete forming, and other rail work. Each of these activities was taken into account to evaluate the regional and localized air quality effects during the construction phase. Analysts also quantified emissions from reconductoring approximately 11.1 miles of the existing single-circuit Spring to Llagas and Green Valley to Llagas 115-kV power lines.

6.4.2 Construction Approach

Construction would proceed south to north, from Carlucci Road to San Jose Diridon Station, although construction would likely proceed in all subsections concurrently. Construction would occur over multiple phases between 2022 and 2028. Tunneling activities would occur up to 7 days per week with up to 24-hour days. All other construction would occur 5 days per week with 10-hour days (250 days per year) (Scholz 2018).

Major construction activities include earthworks and excavation support; tunnel, bridge, and aerial structure construction; station construction; track work; railway systems construction (including traction electrification, signaling, and communications); and testing and commissioning. During peak construction periods, work is envisioned to be underway at several locations along the route, with overlapping construction of various project elements. Working hours and workers present at any time would vary, depending on the activities being performed. Pursuant to its adopted sustainability policy (Policy Directive POLI-PLAN-03), the Authority intends to build the project using sustainable methods that:

- Minimize the use of nonrenewable resources
- Minimize the effects on the natural environment
- Protect environmental diversity
- Emphasize the use of renewable resources in a sustainable manner

6.4.3 Models and Methods for Mass Emissions Modeling

Construction of the project would generate emissions of ROG, NO_X, CO, SO_X, PM_{10}, $PM_{2.5}$, CO_2, CH_4, and N_2O that could result in short-term air quality and GHG effects. Emissions would originate from off-road equipment exhaust, employee and haul truck vehicle exhaust (on-road vehicles), site grading and earth movement, concrete batching, demolition, paving, architectural coating, electricity consumption, and helicopters (for reconductoring work). These emissions would be temporary (i.e., limited to the construction period) and would cease when construction activities are complete.

Combustion exhaust, fugitive dust (PM_{10} and $PM_{2.5}$), and fugitive off-gassing (ROG) were estimated using a combination of emission factors and methods from CalEEMod, version 2016.3.2; the CARB's EMFAC2017 model; and the USEPA's AP-42 Compilation of Air Pollutant Emission Factors based on project-specific construction data (e.g., schedule, equipment, truck volumes) provided by the project engineering team (Scholz 2018). Appendix C provides a complete list of construction assumptions, including equipment, vehicles, and quantities and the construction schedule.

- **Off-road equipment**—Emission factors for off-road construction equipment (e.g., loaders, graders, bulldozers) were obtained from the CalEEMod (version 2016.3.2) User's Guide appendix, which provides values per unit of activity (in grams per horsepower-hour) by calendar year (Trinity Consultants 2016). Analysts estimated criteria pollutants by multiplying the CalEEMod emission factors by the equipment inventory provided by the project engineering team (Scholz 2018).
- **On-road vehicles**—On-road vehicles (e.g., pickup trucks, flatbed trucks) would be required for material and equipment hauling, on-site crew and material movement, and employee commuting. Analysis estimated exhaust emissions from on-road vehicles using the EMFAC2017 emissions model and activity data (miles traveled per day) provided by the project engineering team (Scholz 2018). Emission factors for haul trucks are based on aggregated-speed emission rates for EMFAC's T7 Single vehicle category. Factors for on-site dump, water, boom, and concrete trucks were based on 5 mph emission rates for the T6 Heavy category. Factors for employee commute vehicles were based on a weighted average for all vehicle speeds for EMFAC's light-duty automobile/light-duty truck vehicle categories. CARB's (2019, 2020) SAFE Vehicles Rule adjustment factors were applied to the emission factors for gasoline-powered vehicles. Fugitive re-entrained road dust emissions were estimated using the USEPA's *Compilation of Air Pollutant Emission Factors* (AP-42), Sections 13.2.1 and 13.2.2 (USEPA 2006b, 2011).
- **Site grading and earth movement**—Fugitive dust emissions from earth movement (e.g., site grading, bulldozing, and truck loading) were quantified using emission factors from CalEEMod and USEPA (1998) AP-42. Data on the total graded acreage and quantity of cut-and-fill material were provided by the project engineering team (Scholz 2018).
- **Onsite concrete batch plants**—Fugitive dust emissions from concrete batching at the three new temporary batch plants were quantified using emission factors from BAAQMD's (2016) Permit Handbook and USEPA's AP-42. Daily and annual batch quantities (cubic yards) were provided by the project engineering team (Scholz 2018). Emissions generated by material transport and operation of yard equipment and electricity consumption at onsite batch plants are accounted for in the on-road vehicles, off-road equipment, and electricity consumption analyses discussed in this section.
- **Demolition**—Fugitive dust emissions from building demolition were based on the anticipated amount of square feet to be demolished and calculation methods from the CalEEMod User's Guide (Trinity Consultants 2016).
- **Paving**—Fugitive ROG emissions associated with paving were calculated using activity data (e.g., square feet paved) provided by the project engineer and the CalEEMod default

emission factor of 2.62 pounds of ROG per acre paved (Scholz 2018; Trinity Consultants 2016).

- **Architectural coating**—Fugitive ROG emissions associated with architectural coatings of the stations were calculated using activity data (e.g., square feet coated) provided by the project engineering team and methods in the CalEEMod User's Guide (Scholz 2018; Trinity Consultants 2016). Emissions calculations assume a ROG content of 150 grams per liter (g/L), consistent with BAAQMD's Regulation 8, Rule 3, Section 301.
- **Electricity consumption—**GHG emissions generated by electricity used to power tunnel-boring equipment and temporary batch plants were quantified using activity data (e.g., megawatt hours) provided by the project engineering team and the statewide grid average emission factors (Scholz 2018; USEPA 2020).
- **Helicopters—**Helicopters would be required for the reconductoring work. Exhaust emissions were calculated using emission factors and assumptions derived from a review of guidance manuals published by USEPA (1978) and The Climate Registry (2018).

6.4.4 Ballast and Subballast Hauling

Ballast and subballast materials could be transported from multiple quarry locations throughout Northern California and the Central Valley. Analysts estimated emissions from ballast and subballast material hauling by trucks and locomotives based on the travel distances and transportation method (by rail or by truck) from the locations where ballast materials would be available. Analysts used heavy-duty truck emission factors (T7 Single) from EMFAC2017 to estimate emissions from haul trucks and rail emission factors from the USEPA (2009) to estimate the locomotive emissions.

Analysts identified up to 11 potential quarries that could provide ballast material. All quarries are within the SFBAAB, MBARD, and SJVAPCD, with the furthest quarry located 37 rail miles and 89 highway miles from the project footprint. Ballast and subballast quantities for the project were provided by the project engineering team and distributed equally among the identified quarries (Scholz 2018). Analysts estimated emissions under two hauling scenarios: Scenario 1 assumed ballast and subballast would be hauled to the project footprint using a combination of trucks and locomotives, and Scenario 2 assumed ballast and subballast would be hauled to the project footprint using only trucks. Appendix D provides details of the emission estimates, quarry selection process, and scenario analyses.

6.4.5 Daily and Annual Emissions Estimates

Up to six components (viaduct, embankment, at grade, trench, tunnel, and cut and fill) would be constructed, depending on the subsection and project alternative. Each component would be constructed over multiple phases between 2022 and 2028. Daily criteria pollutant and GHG emissions generated by construction of each phase were quantified using the methods described above. The daily estimates were converted to annual totals based on the detailed construction schedule for each project alternative, which was developed by the project engineering team (Scholz 2018). Maximum daily emissions, based on concurrent construction activity, were also quantified within the BAAQMD and MBARD, consistent with air district requirements (BAAQMD 2017a; MBUAPCD 2008). The highest daily emissions in each construction year were selected as the peak day for analysis purposes. This approach is meant to convey a worst-case scenario based on available information and, therefore, is not necessarily representative of actual emissions that would be incurred on a daily basis throughout the construction period.

6.4.6 Emissions by Air District and Basin

The project falls under the jurisdiction of three air districts—BAAQMD, MBARD, and SJVAPCD—all of which have adopted their own distinct local thresholds of significance. To compare

emissions to the federal and state thresholds, activities occurring within each air district were quantified and analyzed separately.[17]

Emissions generated by construction of subsections that would occur exclusively within one air district (e.g., the San Jose Diridon Station Approach Subsection in the BAAQMD) were wholly assigned to that air district. Emissions estimates for alternatives that span more than one air district were apportioned based on the location of construction activity. For example, construction of the Pacheco Pass Subsection would occur in both the BAAQMD and SJVAPCD. Accordingly, the emissions estimates were apportioned to the BAAQMD and SJVAPCD based on the number of rail miles constructed within each air district. Table 6-4 summarizes the location of each subsection and the air district scaling factors used in the analysis, as appropriate. All reconductoring work would occur in the BAAQMD.

[17] The CARB acknowledges that air basins, in particular the SJVAB, are both contributors and receptors of pollutant transport throughout the state. While technical documents have been published analyzing the transport relationship among California air basins, quantifying the effects of pollutant transport as a result of the project would require detailed projections of future climatic and meteorological conditions. Air districts in the RSA have adopted thresholds and mitigation requirements that are commensurate with expected criteria air pollutant contributions from upwind air basins (CARB 2011).

Table 6-4 Track Miles and Construction Scaling Factors by Air District

Subsection	Alternative 1			Alternative 2			Alternative 3			Alternative 4		
	BAAQMD	MBARD	SJVAPCD	BAAQMD	MBARD	SJVAPCD	BAAQMD	MBARD	SJVAPCD	BAAQMD	MBARD	SJVAPCD

6.4.7 Project Design Features

As discussed in Section 2.3, Impact Avoidance and Minimization Features, the Authority has developed IAMFs that would avoid or minimize potential air quality effects. Because IAMFs are included as part of the project design, they are not considered mitigation, and are included as part of the project construction emissions estimate. Specifically, the following emissions benefits achieved by AQ-IAMF#1 through AQ-IAMF#6 were assumed in the modeling.

- Fugitive dust reductions from earthmoving best management practices (AQ-IAMF#1) (Western Governors' Association 2006).
  - PM from ground disturbance (i.e., scraping and grading activities), 75 percent (Bay Area Air Quality Management District 2017a)
  - PM from unpaved vehicle travel (i.e., re-entrained road dust), 75 percent[18]
  - PM from demolition, 36 percent (Western Governors' Association 2006)
- VOC reductions (93 percent) from application of architectural coatings (AQ-IAMF#2).[19]
- Criteria pollutant and GHG reductions from use of renewable diesel (AQ-IAMF#3) in all off-road diesel-powered engines (Lovegrove and Tadross 2017)
  - CO, 10 percent (Tier 2 tunneling equipment)
  - NO_X, 10 percent (Tier 2 tunneling equipment)
  - PM, 30 percent (all engines)
  - CO_2e, 99 percent (all engines)
- Criteria pollutant and GHG reductions from use of Tier 4 off-road engines (AQ-IAMF#4). Emissions reductions vary by pollutant and equipment type. Emissions were modeled using Tier 4 emission rates from CalEEMod.
- Criteria pollutant and GHG reductions from use of model year 2010 or newer on-road engines in heavy-duty, diesel powered trucks (AQ-IAMF#5). Emissions reductions vary by pollutant, analysis year, and air basin. Emissions were modeled using emission rates derived from the CARB's EMFAC2017 model.
- Fugitive dust reductions from implementation of typical control measures at new concrete batch plants, such as water sprays, enclosures, and hoods (AQ-IAMF#6). Emissions were modeled using USEPA AP-42 controlled emission factors for concrete batch plants.

6.4.8 Regulatory Control Measures

Many of the control measures required by BAAQMD, MBARD, and SJVAPCD rules and regulations are the same or similar to AQ-IAMF#1 and AQ-IAMF#2. Accordingly, no additional reductions from compliance with air district rules were assumed in the emissions modeling.

6.4.9 Construction Health Risk Assessment

Analysts conducted the HRA using the guidelines provided by the OEHHA (2015) for the *Air Toxics Hot Spots Program* and the HRA guidelines developed by the California Air Pollution Control Officers Association (CAPCOA) (2009).The HRA consists of three parts: (1) PM emissions inventory (2) air dispersion modeling to evaluate off-site concentrations of DPM emissions, and (3) assessment of risks associated with predicted concentrations. The following subsections provide descriptions of each component. The quantitative HRA was only performed for construction of the HSR facilities (e.g., alignment, stations and batch plants). The PG&E

[18] Among other controls, this IAMF requires watering unpaved roads three times daily and limiting vehicle speeds. The 75 percent efficacy is based on a 55 percent reduction for watering and a 44 percent reduction for vehicle speed limits (1-(.55*.44)) = 0.75% (Western Governors' Association 2006).

[19] Assumes an uncontrolled ROG content of 150 g/L per BAAQMD Regulation 8, Rule 3, Section 301 and a controlled ROG content of 10 g/L per AQ-IAMF#2.

reconductoring work would be spread throughout the 11.1-mile corridor and would only occur at individual pole locations on a short-term (i.e., few weeks) and temporary basis.

6.4.9.1 Particulate Matter Emissions Inventory

The emissions inventory includes PM emissions generated by heavy-duty equipment and vehicle exhaust, as well as fugitive dust from site grading and soil movement. The particulate constituent analyzed depends on the emission location and associated air district guidance. The BAAQMD (2017a) has adopted cancer and noncancer risk thresholds for DPM, as well as a separate threshold for localized $PM_{2.5}$ emissions. While DPM is a complex mixture of gases and fine particles that includes more than 40 substances listed by the USEPA and CARB as HAPs, OEHHA guidance indicates that the cancer potency factor developed to evaluate cancer risks was based on total (gas and PM) diesel exhaust (OEHHA 2001). The BAAQMD considers DPM as the surrogate for total diesel exhaust, with its guidance requiring that diesel $PM_{2.5}$ emissions serve as the basis for the cancer and noncancer risk calculations in the SFBAAB (Kirk 2016). SJVAPCD (2015a) has adopted slightly different guidance, and requires that diesel PM_{10} emissions serve as the basis for the risk calculations in the SJVAB. Accordingly, the HRA uses $PM_{2.5}$ as a surrogate for DPM in the BAAQMD and PM_{10} as a surrogate for DPM in the SJVAPCD, consistent with air district guidance.

BAAQMD guidance indicates that localized $PM_{2.5}$ risks should be evaluated using total $PM_{2.5}$ exhaust emissions (i.e., emissions from both diesel- and gasoline-powered equipment). SJVAPCD has not adopted a localized $PM_{2.5}$ threshold.

6.4.9.2 Air Dispersion Modeling

The USEPA's AERMOD dispersion model was used to quantify annual average DPM concentrations at nearby receptor locations for each subsection. The modeling approach follows, where applicable, the OEHHA and CAPCOA methodology, but is also consistent with SJVAPCD and BAAQMD methods, as provided in their guidance documents and based on staff consultation (SJVAPCD 2015a; BAAQMD 2012a)[20]

Meteorological Data

Analysts used three representative meteorological datasets, which broadly cover the different meteorological conditions found in the RSA, in the analysis. Table 6-5 shows the assignment for the three datasets. Five recent years of data for each station were used to conduct the analysis within the BAAQMD and MBARD (San Jose, 2009–2013 and San Martin, 2010–2014). Within the SJVAPCD the meteorological modeled derived dataset for Los Banos, 2004–2008 was used in the analysis. Locations north of Gilroy used urban modeling options, whereas all other locations used default rural settings. Appendix E provides additional details on how these datasets were developed.

[20] BAAQMD's conservative modeling guidance was followed for the portion of the project that traverses the MBARD.

Source Parameters

Analysts assumed eight types of construction work areas characterize construction activities and emissions. Further details on how each type of source was modeled are shown in Tables 6-6 and 6-7. Off-site activity, such as long-distance haul trucks for spoils removal and ballast delivery, were modeled as area sources located on both sides of the on-site segment with a width of 12 feet.

Table 6-6 AERMOD Source Parameters (Bay Area Air Quality Management District and Monterey Bay Air Resources District)

Construction Work Area	Source Type	Size of Modeled Area[1]	Release Height (meters)
At grade/berm (on-site)	Area	Actual length x 171 feet	3 (exhaust), 0 (dust)[2]
At grade/berm (off-site)	Area	Actual length x 12 feet	3 (exhaust), 0 (dust)[2]
Aerial (on-site)	Area	Actual length x 171 feet	3 (exhaust), 0 (dust)[2]

I- = Interstate
OSHA = Occupational Safety and Health Administration
[1] Air quality modeling for the berm and at-grade sources are modeled with similar emission source characteristics. The maximum model effects are reported in Section 7.11, Other Localized Construction Effects.
[2] The one tunnel in this subsection had a calculated effective diameter of 167 meters based on twin bore tunnel, length between 0.6 and 2.2 miles and a rail design speed of 250 mph and compliance with minimum OSHA ventilation flow rate of 30 feet/minute.
[3] Two tunnels were modeled in this subsection with a calculated effective diameter of 512 and 472 feet based on twin bore tunnel with a length between 3.1 and 4.7 miles (shorter tunnel) and > 6.2 miles for the longer tunnel with a rail design speed of 250 miles per hour and compliance with minimum OSHA ventilation flow rate of 30 feet/minute. The longer tunnel also included the modeling of emissions from two 4-foot-diameter ventilation shafts with a rain cap cover.

Receptors

Analysts spaced receptors along the edge of each subsection within the BAAQMD and MBARD, with two exceptions: (1) for the trench, an additional 20–30-meter setback distance was allowed based on their limited location, and (2) at the tunnel openings where staging would occur, a 500-foot safety setback distance was used. Per SJVAPCD direction for the rural subsections within San Joaquin County, a 25-meter setback distance was used. Receptor heights were all set to 1.2 meters, consistent with OEHHA (2015) guidance.

6.4.9.3 Risk Calculations

Consistent with the USEPA, CARB, and air district regulatory guidance, the HRA examines cancer and noncancer (chronic)[21] exposure to the surrounding community and uses OEHHA's guidance on risk calculations (OEHHA 2015).

Cancer Risk

Cancer risk is defined as the lifetime probability (chance) of developing cancer from exposure to a carcinogen, typically expressed as the increased chance in 1 million. The default cancer risk calculation for residents and workers is based on the 95th percentile breathing rate, as recommended by the OEHHA. It also accounts for varying sensitivities to exposure based on age. This includes a higher age sensitivity factor for the first 16 years of life, 95th percentile as a breathing rate as a function of age, exposure duration, and adjustment for time spent at home.

The cancer risk occurs exclusively through the inhalation pathway and was calculated using the following equation.

$$\text{Risk} = \frac{(C_{air} * DBR * ED * EF * Conv_1)}{AT} * CPF * ASF * Conv_2)$$

Where

Risk = DPM cancer risk (per million)

C_{air} = Concentration in the air ($\mu g/m^3$), annual average from AERMOD

DBR = Daily breathing rate (liters per kilogram [L/kg] body weight-day)

ED = Exposure duration (years)

EF = Exposure frequency (days/year)

$Conv_1$ = Micrograms to milligrams (mg), liters to cubic meters ([mg/µg] * [m^3/L])

[21] Note that the OEHHA, CARB, BAAQMD, and SJVAPCD have not identified acute health effects from diesel exhaust. Therefore, acute health effects are not included in this analysis.

AT = Averaging time (days)

CPF = Cancer potency factor (mg per kilogram per day [mg/kg-day]$^{-1}$)

ASF = Average age sensitivity factor for resident (unitless)

$Conv_2$ = Risk per million people

Note that the cancer potency factor incorporates worst-case, health-protective assumptions. It was established using data from animal and epidemiological exposure studies and represents the increased chance or probability of developing cancer, assuming continuous lifetime exposure. Analysts also modeled all receptors with "residential" exposure parameters, assuming exposure to construction-generated pollution would begin during the third trimester of gestation. Defining all receptors as "residential" is conservative because it combines the longest exposure duration (third trimester through end of construction) with the highest age sensitivity factors and exposure frequencies (as defined by OEHHA guidance), yielding a worst-case assessment of potential cancer burden for all other receptor types (e.g., schools). The HRA presented in this report is therefore conservative in that it utilizes these worst-case, health-protective assumptions.

Chronic Noncancer Risk

Analysts calculated the noncancer chronic inhalation effects by dividing the annual average concentration by the reference exposure level for DPM. The reference exposure level is defined as the concentration at which no noncancer health effects are anticipated. Consistent with OEHHA (2015) guidance, a reference exposure level of 5 µg/m^3 was assumed in the calculation.

6.4.10 Other Localized Construction Effects

Analysts used the same general approach and guidance as for the HRA (Section 6.4.9) to evaluate localized criteria pollutant effects during construction. The analysis considers both acute (less than 24 hours) and annual emissions effects of all criteria pollutants, as applicable based on the established NAAQS and CAAQS. Note that the quantitative ambient air quality analysis (AAQA) was only performed for construction of the HSR facilities (e.g., alignment, batch plants, stations).

6.4.10.1 Annual Air Quality Effects

The pollutants of concern with established annual standards are NO_2,[22] PM_{10}, and $PM_{2.5}$. Analysts modeled off-site concentrations of these pollutants using the annual mass emissions inventory and the AERMOD dispersion model. NO_X emissions were converted to NO_2, using the Tier 2 ARM2 approach—now the USEPA-preferred approach using the default conversions of minimum of 50 percent as NO_2 at high NO_X concentrations and 90 percent as NO_2 at low concentration levels of NO_X.

6.4.10.2 Acute Air Quality Effects

The following pollutants of concern have established standards based on hourly or daily exposure:

- CO (1 hour and 8 hours)
- PM_{10} and $PM_{2.5}$ (24 hours)

[22] NO_X is both a regional and localized pollutant. Regional effects (i.e., O_3 formation) take place over long distances and time scales and are not analyzed through a localized ambient air quality analysis. Likewise, since ROG is a regional pollutant, it is not addressed in the localized analysis. Rather, O_3 effects (through NO_X and ROG emissions) are addressed through a comparison of project emissions to the air district and federal *de minimis* thresholds (Section 7.9, Construction Mass Emissions Analysis). Localized effects can occur from the conversion of NO_X to NO_2, and these effects are assessed through the localized NO_2 analysis to confirm emissions would not exceed the CAAQS or NAAQS.

- NO_2 (1 hour) (atmospheric conversion of NO_X to NO_2 is estimated using USEPA's regulatory default Tier 2 ARM2 approach with minimum of 20 percent as NO_2 at high NO_X concentrations and 90 percent as NO_2 at low concentration levels of NO_X)
- SO_2 (1 hour and 24 hours)

The approach to modeling the hourly and daily emissions is similar to the annual approach, but it requires an emissions inventory that represents at least a peak-hour emission rate and activities that may overlap in location and time.

Analysts developed a representative maximum emission scenario for air quality hourly and daily effects for each subsection based on maximum activity levels that could take place simultaneously. Up to six types of features were modeled (berm, aerial, at grade, trenching, tunnel, and cut and fill) within each subsection to determine the maximum hourly and daily effect. This section describes each of the major features and their concurrent major elements. The same widths for each construction feature as used in the annual modeling were assumed. However, each construction crew was assumed active over a length of 1,000 feet within a single day.

Berm

The following activities could occur concurrently:

- Excavation (including utility relocation)
- Concrete + retaining walls
- Formwork + earthwork
- Ballast

Both the emissions associated with excavation and concrete + retaining walls can take place on the same day in two adjacent 1,000-foot sections. Formwork + earthwork activity cannot start until retaining walls are complete, so this major element is only modeled as concurrently taking place with the ballast in two adjacent 1,000-foot sections.

Aerial

The following activities could occur concurrently:

- Excavation + cast-in-place and hardware (CIPH)
- Concrete + formwork

These two major elements, excavation + CIPH and concrete + formwork, can take place adjacent to each section, but not in the same section. Thus, the aerial feature modeled only a single scenario with two major elements, excavation + CIPH and concrete + formwork, as two adjacent 1,000-foot sections.

At Grade

The following activities could occur concurrently:

- Utility relocation + demolition + removal
- Track subgrade + track ballast

These major elements, utility + demolition + removal and track subgrade + ballast, were modeled as taking place on the same day in two adjacent 1,000-foot sections. Similarly, track subgrade and ballast were modeled as taking place on the same day in two adjacent 1,000-foot sections.

Trenching

The following activities could occur concurrently:

- Utility relocation + demolition + CIPH + removal of contaminated material
- Excavation for slurry wall
- Excavation for trench + gravel base + rat slab
- Formwork + concrete pour

These four major elements could take place in adjacent 1,000-foot sections under three scenarios on the same day: (1) utility relocation + demolition + CIPH + removal of contaminated material and excavation for slurry wall; (2) excavation for slurry wall and excavation for trench + gravel base + rat slab, and (3) excavation for trench + gravel base + rat slab and formwork + concrete pour. All three scenarios were modeled to determine maximum hourly and daily effects.

Cut and Fill

The following activities could occur concurrently:

- Excavation
- Compact fill and slope finish

These two major elements could take place concurrently on the same day: excavation and compact fill and slope finish. Thus, the large cut-and-fill features were modeled with only a single scenario with two major elements, excavation and compact fill + slope finish, taking place in two adjacent 1,000-foot sections.

Tunnel

The following activities could occur concurrently:

- Form interior walls/upper walls/track bed construction
- Pour interior walls/floor/upper walls/track bed construction

These two major elements were modeled as taking place on the same day in two adjacent 1,000-foot sections within the tunnel.

6.5 Asbestos, Lead-Based Paint, Valley Fever, and Odors

Asbestos causes cancers of the lung and the lining of internal organs, as well as asbestosis and pleural disease, which inhibit lung function. The USEPA is addressing concerns about potential effects of NOA in a number of areas in California. Analysts used the *San Jose to Merced Project Section Geology, Soils, and Seismicity Technical Report* to determine if NOA occurs within the local RSA (Authority 2019d).

Lead-based paint (LBP) may have been used during construction of existing structures throughout the RSA. Analysts considered whether demolition would occur and whether the project would comply with applicable standards for appropriate disposal. The Valley fever and odor analyses are likewise qualitative and considered the potential for receptors to be exposed to C. immitis fungus spores and nuisance odors.

7 AIR QUALITY EFFECTS ANALYSIS

Using the methods described in Chapter 6, this chapter evaluates and discusses the effects of the project on emissions of criteria pollutants, TACs, MSATs, odors, and asbestos generated during operations and construction. This analysis does not identify NEPA and CEQA impacts and significance conclusions; that information is provided in the Final EIR/EIS, Section 3.3, Air Quality and Greenhouse Gases.

7.1 No Project Alternative

Tables 7-1 and 7-2 show estimated emissions under No Project conditions in 2015, 2029, and 2040 under the medium and high ridership scenarios, respectively. As shown in the tables, total emissions for some pollutants would decrease from 2015 to 2040 (VOC, CO, and NO_X). For other pollutants (SO_2, PM_{10}, and $PM_{2.5}$), total emissions would increase from 2015 to 2040. The increase in PM is primarily because of higher VMT, aircraft, and electricity demand brought about by population and economic growth. The increase in SO_2 is primarily related to growth in air travel and power plant production. The decrease in other pollutants are from expected improvements in on-road vehicle engine technology, fuel efficiency, and turnover in older, more heavily polluting vehicles, which would offset emissions increases from higher on-road VMT and aircraft and power plant activity.

Table 7-1 Estimated Statewide Emissions without the Project—Medium Ridership Scenario

Emission Source	VOC (tons/yr)	CO (tons/yr)	NO_X (tons/yr)	SO_2 (tons/yr)	PM_{10} (tons/yr)	$PM_{2.5}$ (tons/yr)

7.2 Statewide and Regional Operational Emissions Analysis

Tables 7-3 and 7-4 show estimated statewide emissions for the medium ridership scenario and the high ridership scenario, respectively, with the project operating in 2015, 2029, and 2040. As shown in the tables, total emissions for some pollutants (VOC, CO, and NO_X) would decrease from 2015 to 2040. For other pollutants (SO_2, PM_{10}, $PM_{2.5}$), total emissions would increase from 2015 to 2040. The estimated statewide emissions burdens with the project would be the same under all project alternatives because the ridership scenarios do not vary by alternative.

Table 7-3 Estimated Statewide Emissions with the Project—Medium Ridership Scenario

Emission Source	VOC (tons/yr)	CO (tons/yr)	NO_X (tons/yr)	SO_2 (tons/yr)	PM_{10} (tons/yr)	$PM_{2.5}$ (tons/yr)
2015

Comparing Tables 7-1 and 7-2 with Tables 7-3 and 7-4 shows that emissions with the project would follow the same general trends as emissions without the project. Emissions from some pollutant sources would decrease by a small percentage despite population and economic growth in California because of advances in engine technology. Emissions from power plants would increase due to the additional project electrical demand.

Table 7-5 summarizes the net change in emissions between the two ridership scenarios with the project (absolute emissions shown in Tables 7-3 and 7-4) and without the project (absolute emissions shown in Tables 7-1 and 7-2) for the 2015 Existing conditions, as well as the 2029 and 2040 No Project conditions. The net change represents the incremental change in emissions because of the project. As shown in Table 7-5, the project is predicted to have a beneficial effect on (i.e., it would reduce) statewide emissions of all pollutants under both ridership scenarios for the 2015 Existing and 2029 and 2040 No Project conditions. It should be noted that the emission savings due to reduced VMT are conservative because they do not consider the recently enacted SAFE Vehicles Rule. The SAFE Vehicles Rule increases criteria pollutant emission rates for light-duty gasoline-powered vehicles. As such, applying the SAFE Vehicles Rule would increase the benefits of the HSR VMT reductions by as much as 4 percent for certain criteria pollutants in 2040 (CARB 2019).

7.2.1 On-Road Vehicles

As shown in Table 7-6 and Table 7-7, the project is predicted to reduce regional VMT and on-road emissions, respectively, as compared to the 2015 Existing conditions, as well as the 2029 and 2040 No Project conditions, under both ridership scenarios, resulting in a beneficial effect on regional air quality. The change in emissions would be the same under all four project alternatives because the ridership is assumed to be the same. As noted above, the mobile source emissions reductions shown in Tables 7-6 and 7-7 are conservative because they do not account for the SAFE Vehicles Rule, which will increase criteria pollutant emissions (and thus the benefits of the HSR VMT reductions) generated by light-duty gasoline-powered vehicles.

The HSR system is predicted to reduce statewide and regional criteria pollutant emissions associated with roadways because travelers would use HSR rather than drive. The on-road vehicle emission analysis is based on VMT changes and associated average daily speed estimates calculated for Santa Clara, San Benito, and Merced Counties. Analysts obtained emission factors from EMFAC2017, using statewide parameters.

For the project, some vehicles may need to travel additional distances to cross the HSR track on new roadway overheads. On average, roadway overpasses would be provided approximately every 2 miles along the track. It is estimated that vehicles would not have to travel more than 1 mile out of direction to cross the HSR tracks. The width of the roadway overheads would accommodate both farm equipment and school buses traveling in opposite lanes. Because of the number of roadway overheads, it is expected that additional distances vehicles would travel to cross the HSR tracks would be negligible relative to regional VMT reductions; therefore, this is not discussed further in the analysis.

7.2.2 Trains

The project would use EMU trains, with the power distributed through the overhead contact system. The HSR system would not produce direct emissions from combustion of fossil fuels and associated emissions. However, trains traveling at high velocities, such as those associated with the HSR system, create sideways turbulence and rear wake, which resuspend particulates from the surface surrounding the track, resulting in fugitive dust emissions. Assuming a friction velocity of 0.62 foot per second to resuspend soils in the RSA, an HSR train passing at 220 mph could resuspend soil particles out to approximately 10 feet from the train (Watson 1996). Based on the USEPA method for estimating emissions from wind erosion (USEPA 2006a), the project would generate approximately 8 to 18 tons per year of PM_{10} and 1 to 3 tons per year of $PM_{2.5}$, depending on the alternative (Section 7.2.5, Regional Operations Criteria Pollutants). Details of the analysis and calculations are provided in Appendix F.

The SFBAAB, NCCAB, and SJVAB regions have high rates of asthma in adults and children. Because the HSR system is electrically powered, it would not generate direct combustion emissions along its route that would cause substantial health concerns such as asthma or other respiratory diseases. Appendix F provides a detailed analysis of wind-induced fugitive dust emissions from HSR travel. Based on this analysis, fugitive dust emissions from HSR travel are not expected to result in amounts of dust to cause health concerns.

7.2.3 Aircraft

The implementation of the project and the HSR system is predicted to reduce the number of aircraft flights at the regional airports in Northern California. Using the methods described in Section 6.2.3, Aircraft, analysts estimated emissions from aircraft takeoff and landing cycles as well as associated ground maintenance requirements. Table 7-8 shows the total number of flights with and without the project in 2015, 2029, and 2040 for both ridership scenarios.

As shown in Table 7-9, the project is predicted to reduce regional and statewide aircraft emissions compared to the 2015 Existing conditions, as well as the 2029 and 2040 No Project conditions, under both ridership scenarios, resulting in a beneficial effect on regional air quality. The effect on emissions would be the same under all four project alternatives because ridership is assumed the same.

7.2.4 Power Plants

The project would increase electrical requirements compared to the 2015 Existing conditions and 2029 and 2040 No Project conditions because the trains would be powered by electricity. Analysts conservatively estimated the statewide electrical demands from propulsion of the trains and the operation of the trains at terminal stations and in storage depots and maintenance facilities. No one-generation source for the electrical power requirements can be identified, because the state's electrical grid would power the HSR system.

Table 7-10 shows the pollutant emissions relative to the 2015 Existing and 2029 and 2040 No Project conditions and indicates the direct effect of the project by comparing the emissions with the project to the emissions that would occur without the project. The effect on emissions would be the same under all four project alternatives because ridership is assumed the same.

As previously noted, the state requires an increasing fraction (60 percent by 2030) of electricity generated for the state's power portfolio to come from renewable energy sources, and the Authority has a policy goal to use 100 percent renewable energy to power the HSR system. However, this analysis conservatively estimates power plant emissions based on the state's existing power portfolio and renewable energy mix. Accordingly, the emissions generated for powering the HSR system are expected to be lower in the future compared to emission estimates used in this analysis.

7.2.5 Regional Operations Criteria Pollutant Emissions Summary

Table 7-11 through Table 7-13 show the total emission changes from project operations under the medium and high ridership scenarios for the 2015 Existing conditions (Table 7-11) and 2029 and 2040 No Project conditions (Tables 7-12 and 7-13). Results include indirect emissions from regional vehicle travel, aircraft, and power plants and direct operations emissions from HSR train movement.

As shown in the tables, all four project alternatives would result in a net regional decrease in emissions of all criteria pollutants. These decreases would be beneficial to the SFBAAB, NCCAB, and SJVAB and help the basins meet their attainment goals for O_3 and other criteria pollutants. Lower ridership would result in fewer regional benefits, although it would still constitute a net benefit. Direct emissions of fugitive dust (PM_{10} and $PM_{2.5}$) from train movement would only occur within the project footprint; however, as discussed, these emissions would be distributed along the entire track length and are not expected to result in substantial concentrations in any one localized area.

The beneficial effects from a reduction in regional operations criteria pollutant emissions would be approximately the same under all four project alternatives. The decrease in indirect emissions associated with regional vehicle travel, aircraft, and power plants would be equal under all four project alternatives because ridership would not vary by alternative. As noted above, emission savings shown in Table 7-11 through Table 7-13 due to reduced VMT are conservative because they do not consider the recently enacted SAFE Vehicles Rule. The SAFE Vehicles Rule increases criteria pollutant emission rates for light-duty gasoline-powered vehicles. As such, applying the SAFE Vehicles Rule would increase the benefits of the HSR VMT reductions by as much as 4 percent for certain criteria pollutants in 2040 (CARB 2019). Direct emissions, which do not depend on ridership, would vary slightly by alternative associated with $PM_{2.5}$ and PM_{10} emissions from HSR train movement, although the effect on overall emissions is negligible. Emissions of the other criteria pollutants would be the same under all four alternatives.

7.3 Local Operation Emission Sources

Operation of the San Jose Diridon, Downtown Gilroy, and East Gilroy Stations and the maintenance facilities would produce criteria pollutant emissions. The operation of the power traction, switching, and paralleling stations would not result in appreciable quantities of air pollutants because site visits would be infrequent, and power usage would be limited. Therefore, emissions from the power traction, switching, and paralleling stations were not quantified.

7.3.1 Station Sites and Maintenance Facilities

Emissions associated with operation of the stations and maintenance facilities are expected because of combustion sources used primarily for space heating and facility landscaping, energy consumption for facility lighting, minor solvent and paint usage for periodic application of architectural coatings, and employee and passenger traffic. Analysts used CalEEMod to estimate these emissions from the stations and maintenance facilities, based on the square footage of the buildings and assumptions described in Chapter 6. Mobile source emissions estimates were adjusted to reflect the impact of the SAFE Vehicles Rule (CARB 2019). Operation of the MOWF would also generate emissions from vehicles, equipment, and locomotives used for maintenance activities. Analysts estimated the criteria pollutant emissions for 2015, 2029, and 2040 conditions and they are included in Table 7-14. Station and maintenance facility emissions would be similar among all four alternatives, but slightly higher under Alternative 3, which includes the East Gilroy Station. Since the East Gilroy Station is entirely new, net emissions are greater than the Downtown Gilroy Station since emissions under existing conditions are zero.

PM_{10} = particulate matter 10 microns or less in diameter
$PM_{2.5}$ = particulate matter 2.5 microns or less in diameter
SO_2 = sulfur dioxide
tons/yr = tons per year
VOC = volatile organic compound
[1] Represents emissions from the existing facilities prior to HSR improvements. The East Gilroy Station, MOWF, and MOWS do not exist under existing conditions, and existing emissions are assumed to be zero.
[2] There would be no difference in operational emissions between the aerial and at-grade options.
[3] There would be no difference in operational emissions between the aerial and embankment options.
[4] There would be no difference in operational emissions between the south and east Gilroy options.

7.4 Total Operations Emissions

Tables 7-15 through 7-17 show a summary of the total emission changes because of HSR operation for the medium and high ridership scenarios, including the indirect emissions from regional vehicle travel, aircraft, and power plants and direct project operational emissions from HSR stations, maintenance facilities, and train movements. The project would result in a net regional decrease in emissions of criteria pollutants. These decreases would be beneficial to the SFBAAB, NCCAB, and SJVAB and help the basins meet their attainment goals for O_3 and particulates (PM_{10} and $PM_{2.5}$). Lower ridership would result in fewer regional benefits, although even with lower ridership, there would be a net benefit.

All four project alternatives would result in a net reduction in operations emissions from the 2015 Existing and 2029 and 2040 No Project conditions, although there would be slight differences in the total emission changes by alternative. Indirect emissions from vehicle travel, aircraft, and power plants are based on ridership, which would not differ by alternative. Direct emissions, including stations, maintenance facilities, and train movement, would vary by alternative although the overall difference is small. As noted above, emission savings shown in Tables 7-15 through 7-17 due to reduced VMT are conservative because they do not consider the recently enacted SAFE Vehicles Rule. The SAFE Vehicles Rule increases criteria pollutant emission rates for light-

duty gasoline-powered vehicles. As such, applying the SAFE Vehicles Rule would increase the benefits of the HSR VMT reductions by as much as 4 percent for certain criteria pollutants in the year 2040 (CARB 2019).

7.5 Microscale Carbon Monoxide Hot-Spot Analysis

Analysts modeled CO concentrations at five intersections covered by covered by congestion management plans identified in the traffic analysis as having the highest station traffic volumes and the worst levels of congestion/delay. In addition to these locations, the intersection of Monterey Road and Skyway Drive was analyzed under Alternative 4, which would require an at-grade crossing. Alternatives 1 through 3 would not worsen traffic conditions at this or other intersections along the alignment because the alignment and roadways would be grade separated.

The modeled CO concentrations were adjusted to reflect the impact of the SAFE Vehicles Rule (CARB 2019) and were combined with CO background concentrations. The total ambient CO concentrations were then compared with air quality standards. Table 7-18 shows the CO hot-spot analysis results and indicates that CO concentrations are not anticipated to exceed the 1- or 8-hour NAAQS and CAAQS. Traffic volumes would not differ significantly among the project alternatives at the five station intersections; consequently, the results presented in Table 7-18 are representative of all four project alternatives. The results for Monterey Road/Skyway Drive are only applicable to Alternative 4.

7.6 Particulate Matter (PM_{10} and $PM_{2.5}$) Hot-Spot Analysis

Compared to the No Project Condition, the project would reduce VMT under all analysis years (2015, 2029, and 2040), resulting in PM_{10} and $PM_{2.5}$ reductions (Table 7-5 and Table 7-6). To identify and evaluate potential effects, analysts prepared a hot-spot analysis because the SFBAAB and SJVAPCD portions of the local RSA are designated nonattainment for the $PM_{2.5}$ NAAQS and maintenance for the PM_{10} NAAQS (SJVAPCD only), and the project is subject to a localized PM_{10} and $PM_{2.5}$ hot-spot analysis. The project alternatives would not differ in PM emissions because the regional change in VMT would be the same for all alternatives.

In November 2015, the USEPA updated its *Transportation Conformity Guidance for Quantitative Hot-Spot Analyses in $PM_{2.5}$ and PM_{10} Nonattainment and Maintenance Areas* (USEPA 2015e), which was used for this analysis. Although this analysis is normally associated with the Transportation Conformity Rule, the HSR system is subject to the General Conformity Rule. Notwithstanding the decision to use this analytical structure, additional analysis or associated activities required to comply with transportation conformity would be carried out only if discrete project elements become subject to those requirements. In accordance with this guidance, if a project meets one of the following criteria, it is considered a project of air quality concern, and a quantitative PM_{10}/$PM_{2.5}$ analysis is required.

- **New or expanded highway projects that have a significant number of or significant increase in number of diesel vehicles**—The project is not a new highway project, nor would it expand an existing highway beyond its current capacity. The HSR system would be electrically powered. While the project would affect traffic conditions on roadways near the stations, it would not measurably affect truck volumes on the affected roadways. Most vehicle trips entering and leaving the station location would be passenger vehicles, which are typically not diesel-powered, except for delivery truck trips to support station activities. Furthermore, the project would improve regional traffic conditions by reducing traffic congestion and regional VMT within the RSA and increasing vehicle speeds.
- **Projects affecting intersections that are at LOS D, E, or F with a significant number of diesel vehicles or those that will degrade to LOS D, E, or F because of increased traffic volumes from a significant number of diesel vehicles related to the project**—The project would not change the existing traffic mix at signalized intersections. Although the maintenance facilities would use diesel vehicles, daily deliveries are not expected to exceed 20 trips. In some cases, the LOS of intersections near the HSR stations or at at-grade crossings (Alternative 4 only) would be degraded to LOS F under the project alternatives. However, the traffic volume increases at the affected intersections would be primarily from passenger cars and transit buses used for transporting people to or from the stations. Passenger cars would be gasoline-powered. Buses operated by VTA are a mix of diesel- and diesel-electric-powered. Pursuant to the Innovative Clean Transit Regulation, VTA's bus fleet will be comprised of only zero-emission vehicles by 2040. While diesel-powered buses would still operate as part of VTA's future vehicle fleet until this time, they would not represent a significant (i.e., less than 5 percent) portion of local traffic.
- **New or expanded bus and rail terminals and transfer points that have a significant number of diesel vehicles congregating at a single location**—The trains used for the project would be EMUs, powered by electricity, not diesel fuel. Most vehicle trips entering and leaving the stations would be passenger vehicles, which are not typically diesel-powered.[23]

  Alternatives 1, 2, and 4 would not have new or expanded bus or rail passenger terminals or transfer points that would significantly increase the number of diesel vehicles congregating at a single location. Improved bus service at the Diridon and Downtown Gilroy stations is not part of the HSR system. The Authority assumes that bus service levels at these locations are

[23] While not a bus or rail terminal, the maintenance facilities would also have diesel vehicles, but these would be limited to 20 or fewer haul vehicles per day. Likewise, locomotives used to support maintenance activities at the MOWF would be used between 24 and 210 hours per year, depending on function.

constant into the future given that no operator has a funding plan to deliver more service. VTA will transition to a zero-emissions bus fleet, which will reduce emissions over time.

While bus service levels are assumed to be the same with and without the project, the East Gilroy Station under Alternative 3 would be an entirely new transit stop with HSR. The project would generate approximately 107 shuttle/bus trips per day at the East Gilroy Station in 2029. These trips would be made by a combination of diesel, diesel-electric, and fully electric buses. While the diesel-powered buses would generate DPM along the bus access route (Leavesley Road) and during passenger loading/unloading, the emissions would be minor, totaling less than 0.0012 pounds of PM_{10} per day (refer to Appendix C). The 107 additional bus trips would represent less than 1.5 percent of average daily traffic on Leavesley Road (Burton 2019). Accordingly, the East Gilroy Station would not significantly increase the number of diesel vehicles congregating at a single location in the near term. By 2040, all transit buses at the East Gilroy Station would be zero-emissions vehicles, pursuant to the Innovative Clean Transit Regulation.

- **Projects in or affecting locations, areas, or categories of sites that are identified in the $PM_{2.5}$- or PM_{10}-applicable implementation plan or implementation plan submission, as appropriate, as sites of violation or possible violation**—The RSA is not in an area identified as a site of violation or possible violation in the USEPA-approved SIP.

For these reasons, the project would not be considered a project of air quality concern as defined by 40 C.F.R. Section 93.123(b)(1) and would not likely cause violations of the PM_{10}/$PM_{2.5}$ NAAQS during its operation. Therefore, quantitative $PM_{2.5}$ and PM_{10} hot-spot evaluations are not required. CAA 40 C.F.R. Section 93.116 requirements are therefore met without a quantitative hot-spot analysis. The project would not likely cause an effect on air quality for PM_{10}/$PM_{2.5}$ standards because, based on these criteria, it is not a project of air quality concern.

7.7 Mobile Source Air Toxics

In accordance with the FHWA's *Interim Guidance Update on Air Toxic Analysis in NEPA Documents,* released September 30, 2009 and updated on October 18, 2016 (FHWA 2016), the qualitative assessment presented in the following subsections is derived, in part, from an FHWA study, *A Methodology for Evaluating Mobile Source Air Toxic Emissions among Transportation Project Alternatives* (FHWA 2011). It is provided as a basis for identifying and comparing the potential differences in MSAT emissions, if any, among the project alternatives.

MSAT emissions would not differ among the project alternatives because the regional change in vehicle emissions would be the same for all alternatives. Therefore, this analysis compares the project to the 2015 Existing Conditions and 2029 and 2040 No Project conditions.

7.7.1 Regional Mobile Source Air Toxics

Under the project, the HSR system would use EMUs, with the power distributed to each train car via the overhead contact system. Operation of the EMUs would not generate combustion emissions; therefore, no toxic emissions would be expected from operation of the project.

The project would decrease regional VMT and MSAT emissions relative to the 2029 and 2040 No Project conditions. The availability of the HSR system would reduce the number of individual vehicle trips on a regional basis. Because the project would not substantially change the regional traffic mix, the amount of MSATs emitted from highways and other roadways within the RSA would be proportional to the VMT. Because the regional VMT estimated for the project would be less than the anticipated VMT in 2029 and 2040 without the project, MSAT emissions from regional vehicle traffic would be less for the project.

The project would also result in reduced traffic congestion and increased vehicle speed when compared to the 2029 and 2040 No Project conditions because more people would use the HSR system instead of driving. According to USEPA's Motor Vehicle Emission Simulator (MOVES) 2014a model, emissions of all priority MSATs, except DPM, decrease as speed increases.

Therefore, the project would result in decreases in MSAT emissions as traffic congestion declines.

Even without the project, emissions in 2029 and 2040 would likely be lower than present levels because of the USEPA's national control programs, which are projected to reduce annual MSAT emissions by 90 percent between 2010 and 2050. Local conditions may differ from these national projections in terms of fleet mix and turnover, VMT growth rates, and local control measures. However, the magnitude of the USEPA-projected reductions is so great (even after accounting for VMT growth relative to existing conditions) that MSAT emissions in the RSA are likely to be lower in the future in nearly all cases.

7.7.2 Local Mobile Source Air Toxics

The potential MSAT emission sources directly related to project operation would be from vehicles used at maintenance facilities and passenger vehicles traveling to and from the train stations. Localized increases in MSAT emissions could occur near the stations because of passenger commutes. Consistent with FHWA's MSAT guidance, the magnitude and the duration of potential changes in localized MSATs cannot be reliably quantified because of incomplete or unavailable information in forecasting project-specific health effects. Even though there may be differences among the project alternatives with respect to localized MSATs, USEPA's vehicle and fuel regulations, coupled with fleet turnover, will cause substantial MSAT reductions over time, thereby offsetting the increase in localized traffic associated with the project.

7.7.3 Mobile Source Air Toxics Research and Incomplete Information

Air toxics analysis is an ongoing area of research. While much work has been done to assess the overall health risk of TACs, many questions remain unanswered. In particular, considerable uncertainties are associated with the existing estimates of MSAT toxicity, as well as the acceptable risk levels. Because of these and other limitations, technical tools are not available to predict the project-specific health effects of the emission changes associated with each project alternative. Because of these limitations, Appendix G is included in this analysis in accordance with CEQ regulations (40 C.F.R. § 1502.22(b)) regarding incomplete or unavailable information.

7.8 Operations Health Risk Assessment

7.8.1 Freight Relocation

Relocated freight service because of the project has the potential to create increased inhalation health risks and exposure to $PM_{2.5}$, which may exceed local significance thresholds for cancer and noncancer hazards at receptor locations adjacent to the relocated track. Health risks to the closest receptors along the relocated track sections were estimated using the BAAQMD's rail inventory tool and the methods described in Section 6.3.7.1. Table 7-19 shows estimated cancer risk, chronic health hazard, and $PM_{2.5}$ concentrations associated with the freight relocation at the analyzed receptor locations.

Table 7-20 shows the incremental change in health risks between the project and existing and No Project conditions and compares those risks to BAAQMD's thresholds. As discussed in Section 6.3.7.1, the analysis assumes the freight relocation would be complete in 2022. Accordingly, emissions exposure under the relocated freight scenario and No Project conditions was assumed to begin in 2022. Existing conditions reflects the risks that would occur if the freight tracks were not relocated and exposure to emissions began in 2015.

As shown in Table 7-20, relocated freight service would generally result in decreased cancer and noncancer health risks, relative to existing conditions. These decreases are primarily because of advancements in locomotive emissions technology and the retirement of older, higher-emitting engines, which reduce future DPM emission rates. The reduction in future locomotive emission rates is enough to offset the increased risk associated with relocating freight service closer to existing receptors.

The comparison of relocated risks to No Project conditions normalizes locomotive emission rates since both conditions assume exposure begins in 2022. Accordingly, the comparison reflects the

incremental project effect, exclusive of background trends. As shown in Table 7-20, relative to no project conditions, relocated freight service would result in minor increases in cancer and noncancer health risks at modeled receptor locations. These increases would not exceed BAAQMD thresholds.

Table 7-20 only evaluates locations where freight would be moved closer to receptors. In many of these locations, receptors on the other side of the track would observe a corresponding health benefit as freight would be moved further away from these receptors.

[2] No Project conditions reflects the risks that would occur if the freight tracks were not relocated and exposure to emissions began in 2022.

7.8.2 Stations and Maintenance Facilities

The Downtown Gilroy and San Jose Diridon Stations would have emergency generators for use in the event of a power outage. The generators would comply with the permitting requirements specified in BAAQMD Regulation 2, Rule 5 and SJVAPCD Rule 2201, which prohibit their operation if cancer or acute hazards exceed air district thresholds. Regulation 2, Rule 5 does not establish any permit restrictions on $PM_{2.5}$ concentrations in the BAAQMD. Accordingly, analysts only estimated $PM_{2.5}$ exhaust concentrations from emergency generator testing because cancer and hazards would be below air district thresholds.

The East Gilroy Station would also operate an emergency generator and would serve diesel-powered buses under 2029 conditions (by 2040, all buses will be net zero emissions per state regulation). Health risks from transit buses are not subject to permit restrictions, and as such, the analysis of health risks at the East Gilroy Station evaluates cancer risk, hazards, and $PM_{2.5}$ concentrations.

The MOWF would operate an emergency generator and use diesel-powered off-road equipment, vehicles, and locomotives to support maintenance and repair activities. The analysis of cancer and noncancer health risks, as well as $PM_{2.5}$ concentrations, at the MOWF includes emissions from all these sources.

Table 7-21 shows the results of health risks analysis at the project stations and the East Gilroy MOWF.[24,25] Health risks and maximum $PM_{2.5}$ concentrations would be less than BAAQMD's health risk thresholds of significance under all alternatives.

[24] The Los Banos MOWS is not analyzed as this facility would be located within the SJVAPCD and the SJVAPCD does not have a $PM_{2.5}$ threshold. SJVAPCD does not issue permits for projects that create a significant cancer or noncancer health risk (SJVAPCD Rule 2201). Accordingly, cancer and noncancer health risks from generator operation at the Los Banos MOWS would be less than SJVAPCD's health risk thresholds.

[25] There are no receptors within 1,000 feet of the South Gilroy MOWF. Accordingly, a health risk assessment is not required, consistent with BAAQMD (2017a) guidance.

Table 7-21 Maximum Health Risks and $PM_{2.5}$ Concentrations from Project Station and MOWF Operation[1]

Source: AERMOD version 18081; HARP 2 version 18159; OEHHA 2015; McGuire 2017–2018, Burton 2019 pers. comm.
HI = hazard index
$PM_{2.5}$ = particulate matter 2.5 microns or less in diameter
$\mu g/m^3$ = micrograms per cubic meter
MOWF = maintenance of way facility
MOWS = maintenance of way siding
SJVAPCD = San Joaquin Valley Air Pollution Control District
[1] The Los Banos MOWS is not analyzed because this facility would be located within the SJVAPCD and the SJVAPCD does not have a $PM_{2.5}$ threshold. SJVAPCD does not issue permits for projects that create a significant cancer or non-cancer health risk.
[2] The San Jose Diridon and Downtown Gilroy Stations were assumed to operate one emergency generator under existing conditions. The East Gilroy Station does not exist under existing conditions and, as such, existing emissions are assumed to be zero.
[3] The expanded San Jose Diridon Station were assumed to operate three emergency generators with implementation of the project. The Downtown Gilroy Station was assumed to operate two emergency generators under project conditions. The East Gilroy Station and MOWF were assumed to operate one generator under project conditions.
[4] There would be no difference in operational emissions or health risk between the aerial and at-grade options.
[5] There would be no difference in operational emissions or health risk between the aerial and embankment options.
[6] Represents the net concentration effect of the project (i.e., the difference in between the existing/no project and the project condition)
[7] There are no receptors within 1,000 feet of the South Gilroy MOWF. Accordingly, a health risk assessment is not required, consistent with BAAQMD (2017a) guidance.

7.9 Construction Mass Emissions Analysis

7.9.1 Total Emissions

Construction activities associated with the project would result in criteria pollutant emissions. This section quantifies and analyzes mass emissions generated by construction. All tables presented in this and subsequent sections reflect the impact of the SAFE Vehicles Rule (CARB 2019).

Construction activities expected to occur during the same calendar year are summarized based on the construction schedule presented in Appendix C. Analysts compared project emissions to the General Conformity *de minimis* emission thresholds on a calendar-year basis; consequently, emissions can exceed thresholds for any calendar year in which emissions occur. No future natural growth or other non-HSR-related improvements are included in project construction effects. Construction emissions for the project alternatives over the entire construction period are shown in Table 7-22. The following sections present detailed tables of emissions by year for each project alternative.

Table 7-22 Total Construction-Related Project Criteria Pollutant Emissions[1]

Alternative/Location	Total Tons									
					PM_{10}			$PM_{2.5}$		
	VOC	NO_X	CO	SO_2	Exhaust	Dust	Total[2]	Exhaust	Dust	Total[2]

BAAQMD = Bay Area Air Quality Management District
CO = carbon monoxide
MBARD = Monterey Bay Air Resources District
NO_X = nitrogen oxide
PM_{10} = particulate matter 10 microns or less in diameter
$PM_{2.5}$ = particulate matter 2.5 microns or less in diameter
SJVAPCD = San Joaquin Valley Air Pollution Control District
SO_2 = sulfur dioxide
VOC = volatile organic compound

[1] Table presents total emissions in tons over the course of complete construction (2022–2028). Emissions results include implementation of AQ-IAMF#1 through AQ-IAMF#6, as described in Section 2.3.
[2] Total PM_{10} and $PM_{2.5}$ emissions consist of exhaust and fugitive dust emissions.

7.9.2 Alternative 1 Yearly and Daily Emissions

Table 7-23, Table 7-24, and Table 7-25 show emissions from Alternative 1 in the BAAQMD, MBARD, and SJVAPCD regions, respectively, in tons per year and pounds per day. Emissions are shown for each year that construction would occur and include the major construction activities discussed in Section 6.4, Construction Emission Calculations. The tables also show applicable General Conformity and CEQA thresholds within the BAAQMD, MBARD, and SJVAPCD, respectively, and indicate whether project construction emissions would exceed these General Conformity and CEQA thresholds.

BAAQMD = Bay Area Air Quality Management District
CEQA = California Environmental Quality Act
CO = carbon monoxide
IAMF = impact avoidance and minimization feature
NAAQS = national ambient air quality standards
NO_X = nitrogen oxide
PM_{10} = particulate matter 10 microns or less in diameter
$PM_{2.5}$ = particulate matter 2.5 microns or less in diameter
SFBAAB = San Francisco Bay Area Air Basin
SO_2 = sulfur dioxide
USEPA = U.S. Environmental Protection Agency
VOC = volatile organic compound
O_3 = ozone
- = no threshold

[1] Emissions results include implementation of air quality IAMFs, as described in Section 2.3.
[2] Presents the highest emissions estimate during a single day of construction in each year, based on concurrent construction activities
[3] Total PM_{10} and $PM_{2.5}$ emissions consist of the exhaust and fugitive dust emissions. Annual values may not add due to rounding. Daily results may not add because the table presents maximum emissions results for each individual pollutant component. For example, the maximum PM exhaust emissions may not occur on the same day as the maximum total dust emissions.
[4] The General Conformity *de minimis* thresholds for criteria pollutants are based on the federal attainment status of the project vicinity in the SFBAAB. The project vicinity is considered a marginal nonattainment area for the O_3 NAAQS and a moderate nonattainment area for the $PM_{2.5}$ NAAQS. Although the project vicinity is in attainment for SO_2, because SO_2 is a precursor for $PM_{2.5}$, the $PM_{2.5}$ General Conformity *de minimis* thresholds are used.

O_3 = ozone

[1] Emissions results include implementation of air quality IAMFs, as described in Section 2.3.
[2] Presents the average emissions estimate during a single day of construction in each year. Average emissions are presented in SJVAPCD (rather than maximum emissions), consistent with (SJVAPCD 2015a) guidance for correct application of its 100-pound-per-day AAQA screening criteria.
[3] Total PM_{10} and $PM_{2.5}$ emissions consist of the exhaust and fugitive dust emissions. Annual values may not add due to rounding. Daily results may not add because the table presents maximum emissions results for each individual pollutant component. For example, the maximum PM exhaust emissions may not occur on the same day as the maximum total dust emissions.
[4] The General Conformity *de minimis* thresholds for criteria pollutants are based on the federal attainment status of the project vicinity in the SJVAB. The project vicinity is considered an extreme nonattainment area for the O_3 NAAQS, a serious/moderate nonattainment area for the $PM_{2.5}$ NAAQS, and a serious maintenance area for the PM_{10} NAAQS. Although the project vicinity is in attainment for SO_2, because SO_2 is a precursor for $PM_{2.5}$, the $PM_{2.5}$ General Conformity *de minimis* thresholds are used.
[5] The 100-pound-per-day threshold is a screening-level threshold to help determine whether increased emissions from a project will cause or contribute to a violation of CAAQS or NAAQS. Projects with emissions below the threshold will not be in violation of CAAQS or NAAQS. Projects with emissions above the threshold would require an AAQA to confirm this conclusion (SJVAPCD 2015a).

This Page Intentionally Left Blank

The emissions results demonstrated that construction of Alternative 1 would result in ROG and NO_X emissions that would exceed the BAAQMD's CEQA thresholds, as well as SJVAPCD's annual CEQA thresholds for NO_X, CO, and PM_{10}. Construction of Alternative 1 would also exceed the general conformity *de minimis* NO_X thresholds in the SFBAAB and SJVAB.

Construction emissions would also exceed SJVAPCD's daily AAQA screening trigger for NO_X, CO, and PM_{10}. Localized effects from these pollutants are evaluated based on the air dispersion modeling of ambient air concentrations. Section 7.11 presents the modeled ambient air concentrations relative to the NAAQS and CAAQS.

Project features (AQ-IAMF#1 through AQ-IAMF#6) would minimize air quality effects through application of best available on-site controls to reduce construction emissions. However, even with these measures, exceedances of air district and general conformity *de minimis* thresholds would still occur. AQ-MM#1 identifies additional best management practices for reducing on-site fugitive dust emissions, consistent with BAAQMD (2017a) guidance. AQ-MM#2 requires that a minimum of 25 percent of all light-duty on-road vehicles use ZE or NZE technology. The measure also includes ZE and NZE goals for heavy-duty on-road trucks and off-road equipment. The commercial availability of future ZE and NZE off-road equipment and heavy-duty vehicles in the California market is uncertain but expected to improve given technological advancements and regulations. Therefore, in addition to the minimum light-duty on-road vehicle ZE and NZE requirement of 25 percent, AQ-MM#2 includes ZE and NZE goals for off-road equipment and heavy-duty vehicles. ZE and NZE equipment and vehicles do not directly generate, or generate only minimal criteria pollutants, and thus AQ-MM#2 will reduce the severity of this impact. However, because the penetration of ZE and NZE off-road equipment and heavy-duty vehicles in future construction fleets is unknown, emissions reductions achieved by this measure cannot currently be quantified.

ROG and NO_X emissions would be offset in the BAAQMD through the purchase of offsets (AQ-MM#3: Offset Project Construction Emissions in the San Francisco Bay Area Air Basin) to below BAAQMD thresholds or net zero (as required by the General Conformity regulation). ROG, NO_X, and PM emissions would be fully offset (i.e., to net zero) within the SJVAPCD, pursuant to the Authority's MOU with the air district for the HSR subsections within the SJVAB (AQ-MM#4: Offset Project Construction Emissions in the San Joaquin Valley Air Basin). Pursuant to SJVAPCD's GAMAQI, emissions offsets procured through AQ-MM#4 cannot be used to mitigate CO impacts. Accordingly, CO emissions would remain above SJVAPCD's CEQA threshold even after implementation of all feasible mitigation.

7.9.3 Alternative 2 Yearly and Daily Emissions

Table 7-26, Table 7-27, and Table 7-28 show yearly emissions from Alternative 2 in the BAAQMD, MBARD, and SJVAPCD, respectively, in tons per year and pounds per day. Emissions are shown for each year that construction would occur and include the major construction activities discussed in Section 6.4. The tables also show applicable General Conformity and CEQA thresholds within the BAAQMD, MBARD, and SJVAPCD, respectively, and indicate whether project construction emissions would exceed these General Conformity and CEQA thresholds.

This Page Intentionally Left Blank

Table 7-26 Construction-Related Criteria Pollutant Emissions under Alternative 2 in the Bay Area Air Quality Management District[1]

CO = carbon monoxide
IAMF = impact avoidance and minimization feature

[1] Emissions results include implementation of air quality IAMFs, as described in Section 2.3.
[2] Presents the highest emissions estimate during a single day of construction in each year, based on concurrent construction activities
[3] Total PM_{10} and $PM_{2.5}$ emissions consist of the exhaust and fugitive dust emissions. Annual values may not add due to rounding. Daily results may not add because the table presents maximum emissions results for each individual pollutant component. For example, the maximum PM exhaust emissions may not occur on the same day as the maximum total dust emissions.
[4] The General Conformity *de minimis* thresholds for criteria pollutants are based on the federal attainment status of the project vicinity in the SFBAAB. The project vicinity is considered a marginal nonattainment area for the O_3 NAAQS and a moderate nonattainment area for the $PM_{2.5}$ NAAQS. Although the project vicinity is in attainment for SO_2, because SO_2 is a precursor for $PM_{2.5}$, the $PM_{2.5}$ General Conformity *de minimis* thresholds are used.

[1] Emissions results include implementation of air quality IAMFs, as described in Section 2.3.
[2] Presents the highest emissions estimate during a single day of construction in each year, based on concurrent construction activities
[3] Total PM_{10} and $PM_{2.5}$ emissions consist of the exhaust and fugitive dust emissions. Annual values may not add due to rounding. Daily results may not add because the table presents maximum emissions results for each individual pollutant component. For example, the maximum PM exhaust emissions may not occur on the same day as the maximum total dust emissions.
[4] The NCCAB is considered attainment for all criteria pollutants. As such, a general conformity analysis is not required, and there are no applicable *de minimis* thresholds.
[5] According to the MBARD CEQA guidelines, construction projects that temporarily emit precursors of O_3 (i.e., ROG or NO_X) are accommodated in the emission inventories of state- and federally required air plans and would not have a significant impact on the attainment and maintenance of state or federal O_3 ambient air quality standards (MBUAPCD 2008).

- = no threshold

[1] Emissions results include implementation of air quality IAMFs, as described in Section 2.3.

[2] Presents the average emissions estimate during a single day of construction in each year. Average emissions are presented in SJVAPCD (rather than maximum emissions), consistent with (SJVAPCD 2015a) guidance for correct application of its 100-pound-per-day AAQA screening criteria.

[3] Total PM_{10} and $PM_{2.5}$ emissions consist of the exhaust and fugitive dust emissions. Annual values may not add due to rounding. Daily results may not add because the table presents maximum emissions results for each individual pollutant component. For example, the maximum PM exhaust emissions may not occur on the same day as the maximum total dust emissions.

[4] The General Conformity *de minimis* thresholds for criteria pollutants are based on the federal attainment status of the project vicinity in the SJVAB. The project vicinity is considered an extreme nonattainment area for the O_3 NAAQS, a serious/moderate nonattainment area for the $PM_{2.5}$ NAAQS, and a serious maintenance area for the PM_{10} NAAQS. Although the project vicinity is in attainment for SO_2, because SO_2 is a precursor for $PM_{2.5}$, the $PM_{2.5}$ General Conformity *de minimis* thresholds are used.

[5] The 100-pound-per-day threshold is a screening-level threshold to help determine whether increased emissions from a project will cause or contribute to a violation of CAAQS or NAAQS. Projects with emissions below the threshold will not be in violation of CAAQS or NAAQS. Projects with emissions above the threshold would require an AAQA to confirm this conclusion (SJVAPCD 2015a).

This Page Intentionally Left Blank

The emissions results demonstrated that construction of Alternative 2 would result in ROG and NO_X emissions that would exceed the BAAQMD's CEQA thresholds, as well as SJVAPCD's annual CEQA thresholds for NO_X, CO, and PM_{10}. Construction of Alternative 2 would also exceed the general conformity *de minimis* NO_X thresholds in the SFBAAB and SJVAB.

Construction emissions would also exceed SJVAPCD's daily AAQA screening trigger for NO_X, CO, and PM_{10}. Localized effects from these pollutants are evaluated based on the air dispersion modeling of ambient air concentrations. Section 7.11 presents the modeled ambient air concentrations relative to the NAAQS and CAAQS.

Project features (AQ-IAMF#1 through AQ-IAMF#6) would minimize air quality effects through application of best available on-site controls to reduce construction emissions. However, even with these measures, exceedances of air district and general conformity *de minimis* thresholds would still occur. AQ-MM#1 identifies additional best management practices for reducing on-site fugitive dust emissions, consistent with BAAQMD (2017a) guidance. AQ-MM#2 requires that a minimum of 25 percent of all light-duty on-road vehicles use ZE or NZE technology. The measure also includes ZE and NZE goals for heavy-duty on-road trucks and off-road equipment. The commercial availability of future ZE and NZE off-road equipment and heavy-duty vehicles in the California market is uncertain but expected to improve given technological advancements and regulations. Therefore, in addition to the minimum light-duty on-road vehicle ZE and NZE requirement of 25 percent, AQ-MM#2 includes ZE and NZE goals for off-road equipment and heavy-duty vehicles. ZE and NZE equipment and vehicles do not directly generate, or generate only minimal criteria pollutants, and thus AQ-MM#2 will reduce the severity of this impact. However, because the penetration of ZE and NZE off-road equipment and heavy-duty vehicles in future construction fleets is unknown, emissions reductions achieved by this measure cannot currently be quantified.

ROG and NO_X emissions would be offset in the BAAQMD through the purchase of offsets (AQ-MM#3) to below BAAQMD thresholds or net zero (as required by the General Conformity regulation). ROG, NO_X, and PM emissions would be fully offset (i.e., to net zero) within the SJVAPCD, pursuant to the Authority's MOU with the air district for the HSR subsections within the SJVAB (AQ-MM#4). Pursuant to SJVAPCD's GAMAQI, emissions offsets procured through AQ-MM#4 cannot be used to mitigate CO effects. Accordingly, CO emissions would remain above SJVAPCD's CEQA threshold even after implementation of all feasible mitigation.

7.9.4 Alternative 3 Yearly and Daily Emissions

Table 7-29, Table 7-30, and Table 7-31 show yearly emissions from Alternative 3 in the BAAQMD, MBARD, and SJVAPCD, respectively, in tons per year and pounds per day. Emissions are shown for each year that construction would occur and include the major construction activities discussed in Section 6.4. The tables also show applicable General Conformity and CEQA thresholds within the BAAQMD, MBARD, and SJVAPCD, respectively, and indicate whether project construction emissions would exceed these General Conformity and CEQA thresholds.

VOC = volatile organic compound
- = no threshold

[1] Emissions results include implementation of air quality IAMFs, as described in Section 2.3.

[2] Presents the highest emissions estimate during a single day of construction in each year, based on concurrent construction activities

[3] Total PM_{10} and $PM_{2.5}$ emissions consist of the exhaust and fugitive dust emissions. Annual values may not add due to rounding. Daily results may not add because the table presents maximum emissions results for each individual pollutant component. For example, the maximum PM exhaust emissions may not occur on the same day as the maximum total dust emissions.

[4] The General Conformity *de minimis* thresholds for criteria pollutants are based on the federal attainment status of the project vicinity in the SFBAAB. The project vicinity is considered a marginal nonattainment area for the O_3 NAAQS and a moderate nonattainment area for the $PM_{2.5}$ NAAQS. Although the project vicinity is in attainment for SO_2, because SO_2 is a precursor for $PM_{2.5}$, the $PM_{2.5}$ General Conformity *de minimis* thresholds are used.

CEQA = California Environmental Quality Act
CO = carbon monoxide
IAMF = impact avoidance and minimization feature
NCCAB = North Central Coast Air Basin
MBARD = Monterey Bay Air Resources District
NO_X = nitrogen oxide
O_3 = ozone
$PM_{2.5}$ = particulate matter 2.5 microns or less in diameter
PM_{10} = particulate matter 10 microns or less in diameter
ROG = SO_2 = sulfur dioxide
VOC = volatile organic compound
- = no threshold

[1] Emissions results include implementation of air quality IAMFs, as described in Section 2.3.
[2] Presents the highest emissions estimate during a single day of construction in each year, based on concurrent construction activities.
[3] Total PM_{10} and $PM_{2.5}$ emissions consist of the exhaust and fugitive dust emissions. Annual values may not add due to rounding. Daily results may not add because the table presents maximum emissions results for each individual pollutant component. For example, the maximum PM exhaust emissions may not occur on the same day as the maximum total dust emissions.
[4] The NCCAB is considered attainment for all criteria pollutants. As such, a general conformity analysis is not required. and there are no applicable *de minimis* thresholds.
[5] According to the MBARD CEQA guidelines, construction projects that temporarily emit precursors of O_3 (i.e., ROG or NO_X) are accommodated in the emission inventories of state- and federally required air plans and would not have a significant impact on the attainment and maintenance of state or federal ozone ambient air quality standards (MBUAPCD 2008).

[1] Emissions results include implementation of air quality IAMFs, as described in Section 2.3.
[2] Presents the average emissions estimate during a single day of construction in each year. Average emissions are presented in SJVAPCD (rather than maximum emissions), consistent with (SJVAPCD 2015a) guidance for correct application of its 100-pound-per-AAQA screening criteria.
[3] Total PM_{10} and $PM_{2.5}$ emissions consist of the exhaust and fugitive dust emissions. Annual values may not add due to rounding. Daily results may not add because the table presents maximum emissions results for each individual pollutant component. For example, the maximum PM exhaust emissions may not occur on the same day as the maximum total dust emissions.
[4] The General Conformity *de minimis* thresholds for criteria pollutants are based on the federal attainment status of the project vicinity in the SJVAB. The project vicinity is considered an extreme nonattainment area for the O_3 NAAQS, a serious/moderate nonattainment area for the $PM_{2.5}$ NAAQS, and a serious maintenance area for the PM_{10} NAAQS. Although the project vicinity is in attainment for SO_2, because SO_2 is a precursor for $PM_{2.5}$, the $PM_{2.5}$ General Conformity *de minimis* thresholds are used.
[5] The 100-pound-per-day threshold is a screening-level threshold to help determine whether increased emissions from a project will cause or contribute to a violation of CAAQS or NAAQS. Projects with emissions below the threshold will not be in violation of CAAQS or NAAQS. Projects with emissions above the threshold would require an AAQA to confirm this conclusion (SJVAPCD 2015a).

This Page Intentionally Left Blank

The emissions results demonstrated that construction of Alternative 3 would result in ROG and NO_X emissions that would exceed the BAAQMD's CEQA thresholds, and NO_X, CO, and PM_{10} emissions that would exceed SJVAPCD's annual CEQA thresholds. Construction of Alternative 3 would also exceed the general conformity *de minimis* NO_X thresholds in the SFBAAB and SJVAB.

Construction emissions would also exceed SJVAPCD's daily AAQA screening trigger for NO_X, CO, and PM_{10}. Localized effects from these pollutants are evaluated based on the air dispersion modeling of ambient air concentrations. Section 7.11 presents the modeled ambient air concentrations relative to the NAAQS and CAAQS.

Project features (AQ-IAMF#1 through AQ-IAMF#6) would minimize air quality effects through application of all best available on-site controls to reduce construction emissions. However, even with these measures, exceedances of air district and general conformity *de minimis* thresholds would still occur. AQ-MM#1 identifies additional best management practices for reducing on-site fugitive dust emissions, consistent with BAAQMD (2017a) guidance. AQ-MM#2 requires that a minimum of 25 percent of all light-duty on-road vehicles use ZE or NZE technology. The measure also includes ZE and NZE goals for heavy-duty on-road trucks and off-road equipment. The commercial availability of future ZE and NZE off-road equipment and heavy-duty vehicles in the California market is uncertain but expected to improve given technological advancements and regulations. Therefore, in addition to the minimum light-duty on-road vehicle ZE and NZE requirement of 25 percent, AQ-MM#2 includes ZE and NZE goals for off-road equipment and heavy-duty vehicles. ZE and NZE equipment and vehicles do not directly generate, or generate only minimal criteria pollutants, and thus AQ-MM#2 will reduce the severity of this impact. However, because the penetration of ZE and NZE off-road equipment and heavy-duty vehicles in future construction fleets is unknown, emissions reductions achieved by this measure cannot currently be quantified.

ROG and NO_X emissions would be offset in the BAAQMD through the purchase of offsets (AQ-MM#3) to below BAAQMD thresholds or net zero (as required by the General Conformity regulation. ROG, NO_X, and PM emissions would be fully offset (i.e., to net zero) within the SJVAPCD, pursuant to the Authority's MOU with the air district for the HSR subsections within the SJVAB (AQ-MM#4). Pursuant to SJVAPCD's GAMAQI, emissions offsets procured through AQ-MM#4 cannot be used to mitigate CO effects. Accordingly, CO emissions would remain above SJVAPCD's CEQA threshold even after implementation of all feasible mitigation.

7.9.5 Alternative 4 Yearly and Daily Emissions

Table 7-32, Table 7-33, and Table 7-34 show yearly emissions from Alternative 4 in the BAAQMD, MBARD, and SJVAPCD, respectively, in tons per year and pounds per day. Emissions are shown for each year that construction would occur and include the major construction activities discussed in Section 6.4. The tables also show applicable General Conformity and CEQA thresholds within the BAAQMD, MBARD, and SJVAPCD, respectively, and indicate whether project construction emissions would exceed these General Conformity and CEQA thresholds.

CEQA = California Environmental Quality Act
CO = carbon monoxide
IAMF = impact avoidance and minimization feature
NCCAB = North Central Coast Air Basin
MBARD = Monterey Bay Air Resources District
NO_X = nitrogen oxide
O_3 = ozone
$PM_{2.5}$ = particulate matter 2.5 microns or less in diameter
PM_{10} = particulate matter 10 microns or less in diameter
ROG = SO_2 = sulfur dioxide
VOC = volatile organic compound
- = no threshold

[1] Emissions results include implementation of air quality IAMFs, as described in Section 2.3.
[2] Presents the highest emissions estimate during a single day of construction in each year, based on concurrent construction activities.
[3] Total PM_{10} and $PM_{2.5}$ emissions consist of the exhaust and fugitive dust emissions. Annual values may not add due to rounding. Daily results may not add because the table presents maximum emissions results for each individual pollutant component. For example, the maximum PM exhaust emissions may not occur on the same day as the maximum total dust emissions.
[4] The NCCAB is considered attainment for all criteria pollutants. As such, a general conformity analysis is not required. and there are no applicable *de minimis* thresholds.
[5] According to the MBARD CEQA guidelines, construction projects that temporarily emit precursors of O_3 (i.e., ROG or NO_X) are accommodated in the emission inventories of state- and federally required air plans and would not have a significant impact on the attainment and maintenance of state or federal ozone ambient air quality standards (MBUAPCD 2008).

AAQA = ambient air quality analysis
CAAQS = California ambient air quality standards
CEQA = California Environmental Quality Act
CO = carbon monoxide
IAMF = impact avoidance and minimization feature
NAAQS = national ambient air quality standards
NO_X = nitrogen oxide
O_3 = ozone
PM_{10} = particulate matter 10 microns or less in diameter
$PM_{2.5}$ = particulate matter 2.5 microns or less in diameter
SJVAPCD = San Joaquin Valley Air Pollution Control District
SO_2 = sulfur dioxide
VOC = volatile organic compound
- = no threshold

[1] Emissions results include implementation of air quality IAMFs, as described in Section 2.3.

[2] Presents the average emissions estimate during a single day of construction in each year. Average emissions are presented in SJVAPCD (rather than maximum emissions), consistent with (SJVAPCD 2015a) guidance for correct application of its 100-pound-per-AAQA screening criteria.

[3] Total PM_{10} and $PM_{2.5}$ emissions consist of the exhaust and fugitive dust emissions. Annual values may not add due to rounding. Daily results may not add because the table presents maximum emissions results for each individual pollutant component. For example, the maximum PM exhaust emissions may not occur on the same day as the maximum total dust emissions.

[4] The General Conformity *de minimis* thresholds for criteria pollutants are based on the federal attainment status of the project vicinity in the SJVAB. The project vicinity is considered an extreme nonattainment area for the O_3 NAAQS, a serious/moderate nonattainment area for the $PM_{2.5}$ NAAQS, and a serious maintenance area for the PM_{10} NAAQS. Although the project vicinity is in attainment for SO_2, because SO_2 is a precursor for $PM_{2.5}$, the $PM_{2.5}$ General Conformity *de minimis* thresholds are used.

[5] The 100-pound-per-day threshold is a screening-level threshold to help determine whether increased emissions from a project will cause or contribute to a violation of CAAQS or NAAQS. Projects with emissions below the threshold will not be in violation of CAAQS or NAAQS. Projects with emissions above the threshold would require an AAQA to confirm this conclusion (SJVAPCD 2015a).

This Page Intentionally Left Blank

The emissions results demonstrated that construction of Alternative 4 would result in ROG and NO_X emissions that would exceed the BAAQMD's CEQA thresholds, as well as SJVAPCD's annual CEQA thresholds for NO_X, CO, and PM_{10}. Construction of Alternative 4 would also exceed the general conformity *de minimis* NO_X thresholds in the SFBAAB and SJVAB.

Construction emissions would also exceed SJVAPCD's daily AAQA screening trigger for NO_X, CO, and PM_{10}. Localized effects from these pollutants are evaluated based on the air dispersion modeling of ambient air concentrations. Section 7.11 presents the modeled ambient air concentrations relative to the NAAQS and CAAQS.

Project features (AQ-IAMF#1 through AQ-IAMF#6) would minimize air quality effects through application of all best available on-site controls to reduce construction emissions. However, even with these measures, exceedances of air district and general conformity *de minimis* thresholds would still occur. AQ-MM#1 identifies additional best management practices for reducing on-site fugitive dust emissions, consistent with BAAQMD (2017a) guidance. AQ-MM#2 requires that a minimum of 25 percent of all light-duty on-road vehicles use ZE or NZE technology. The measure also includes ZE and NZE goals for heavy-duty on-road trucks and off-road equipment. The commercial availability of future ZE and NZE off-road equipment and heavy-duty vehicles in the California market is uncertain but expected to improve given technological advancements and regulations. Therefore, in addition to the minimum light-duty on-road vehicle ZE and NZE requirement of 25 percent, AQ-MM#2 includes ZE and NZE goals for off-road equipment and heavy-duty vehicles. ZE and NZE equipment and vehicles do not directly generate, or generate only minimal criteria pollutants, and thus AQ-MM#2 will reduce the severity of this impact. However, because the penetration of ZE and NZE off-road equipment and heavy-duty vehicles in future construction fleets is unknown, emissions reductions achieved by this measure cannot currently be quantified.

ROG and NO_X emissions would be offset in the BAAQMD through the purchase of offsets (AQ-MM#3) to below BAAQMD or net zero (as required by the General Conformity regulation). ROG, NO_X, and PM emissions would be fully offset (i.e., to net zero) within the SJVAPCD, pursuant to the Authority's MOU with the air district for the HSR subsections within the SJVAB (AQ-MM#4). Pursuant to SJVAPCD's GAMAQI, emissions offsets procured through AQ-MM#4 cannot be used to mitigate CO effects. Accordingly, CO emissions would remain above SJVAPCD's CEQA threshold even after implementation of all feasible mitigation.

7.10 Construction Health Risk Assessment

During construction, sensitive receptors (e.g., schools, residences, and health care facilities) could be exposed to increased concentrations of TAC, such as DPM, that may present increased cancer risks and other health hazards. This section reports and identifies the health risk from the emissions generated by construction.

The analysis considers both acute and chronic noncancer health hazards and increased cancer risk for each project alternative and subsection. Acute risks are based on the maximum daily emissions that could occur across all calendar years. Chronic health risks are based on the maximum annual emissions from all calendar years. Cancer risk is defined as the predicted risk of cancer (unitless) over a lifetime and is expressed as chances per million persons exposed.

DPM is the primary TAC released from construction activities. The modeled DPM concentrations were used in determining the total exposure dose and associated health effect. Specific details of the air dispersion modeling and HRA are provided in Appendix E.

Tables 7-35 through 7-37 present the results of the HRA within the BAAQMD, MBARD, and SJVAPCD, respectively. Maximum predicted risks for each subsection are compared to the local air district significance criteria and indicate no air district risk criteria would be exceeded for any of the four project alternatives. The results represent the highest modeled risk at a receptor location from combined construction of all features (e.g., at grade, viaduct). Consistent with BAAQMD guidance, Table 7-35 also presents the maximum incremental $PM_{2.5}$ concentration generated by project construction. The tables include implementation of AQ-IAMF#1 through AQ-IAMF#6.

7.11 Other Localized Construction Effects[26]

Construction emissions have the potential to cause elevated criteria pollutant concentrations. These elevated concentrations may cause or contribute to exceedances of the NAAQS and CAAQS. This section reports and identifies the criteria air pollutant concentrations from the emissions generated by construction.

Background pollutant concentrations vary by location along the alignment. Table 7-38 reports the background concentrations by pollutant and applicable averaging period for three locations within the RSA. The ambient air quality standards are provided for reference. Existing violations of the standards are shown in bold.

Tables 7-39 through 7-46 present the estimated maximum hourly (< 24 hours) and daily concentrations relative to the CAAQS and NAAQS for Alternatives 1, 2, 3, and 4. Tables 7-47 through 7-50 present the estimated maximum annual concentrations. The tables present both the incremental project and total pollutant concentration; only the total pollutant concentration, which reflects the incremental project contribution plus the background concentration, is compared with the CAAQS and NAAQS to determine if construction would cause an ambient air quality violation.[27]

As shown in Table 7-38, background concentrations of PM_{10} and $PM_{2.5}$ along most of the project already exceed hourly, daily, and annual $PM_{2.5}$ and PM_{10} ambient air quality standards. Table 7-51 compares the incremental project increase in PM concentrations within these areas with the applicable USEPA significant impact levels (SIL)[28] to analyze the potential for the project to worsen existing $PM_{2.5}$ and PM_{10} violations.

All tables include implementation of AQ-IAMF#1 through AQ-IAMF#6. However, because the penetration of ZE and NZE off-road equipment and heavy-duty vehicles in future construction fleets is unknown, emissions reductions achieved by AQ-MM#2 cannot currently be quantified or included in the analysis.

[26] Refinements were made to the particulate matter mass emissions inventory to more comprehensively capture emissions reductions that will be achieved through implementation of AQ-IAMF#1: Fugitive Dust Emissions. These revisions were made for the final air quality analysis, as reported in Tables 7-22 through 7-34 in Section 7.9, Construction Mass Emissions Analysis. Concentration modeling for localized particulate matter was performed prior to the refinement. Accordingly, the particulate matter results shown in Tables 7-39 through 7-51 in this section are conservative.

[27] Project construction does not include any sources that would generate Pb. Pb would be emitted by the three new temporary batch plants, although concentrations would not exceed 1.96E-08 $\mu g/m^3$ for the quarterly standard, 6.72E-07 $\mu g/m^3$ for the 1-hour standard, 1.09E-07 $\mu g/m^3$ for the 8-hour standard, nor 6.14E-08 $\mu g/m^3$ for the 24-hour standard which are well below the NAAQS and CAAQS. Accordingly, a detailed analysis of Pb-related emissions was not conducted.

[28] While the $PM_{2.5}$ SILs have not been officially approved by the USEPA or the SJVAPCD, the air districts suggest that, for illustrative purposes, the analysis consider the USEPA's proposed SILs.

CO = carbon monoxide
MOWF = maintenance of way facility
MOWS = maintenance of way siding
NAAQS = national ambient air quality standards
NO_2 = nitrogen oxide
PM_{10} = particulate matter 10 microns or less in diameter
SIL = significant impact level
µg/m³ = micrograms per cubic meter of air
N/A = Not applicable. Batch plants only have particulate matter emissions

[1] Only the highest modeled concentration is presented for each pollutant. Values have been rounded. In some cases, the rounded value may appear to violate the ambient air quality standard. Only those results shown in underline with an asterisk (*) actually violate the standard.
[2] Represents the maximum incremental off-site concentration from project construction.
[3] A background 1-hour CO concentration of 2,749, 4,812, and 6,644. µg/m³ (for the locations of San Jose – Jackson St., Salinas – Laurel Dr, and Madera – Rd. 29 1/2, respectively) was added to the maximum increment off-site project contribution.
[4] A background 8-hour CO concentration of 2,062, 1,031, and 3,551 µg/m³ (for the locations of San Jose – Jackson St., Salinas – Laurel Dr, and Madera – Rd. 29 1/2, respectively) was added to the maximum increment off-site project contribution.
[5] A background 1-hour NO_2 concentration of 127.84, 62.04, and 73.32 µg/m³ (for the locations of San Jose – Jackson St., Salinas – Laurel Dr, and Merced – S. Coffee, respectively) was added to the maximum increment off-site project contribution.
[6] A background 24-hour PM_{10} concentration of 69, 80, and 146 µg/m³ (for the locations of San Jose – Jackson St., Hollister – Fairview Dr, and Merced – M St, respectively) was added to the maximum increment off-site project contribution.
[7] A background 1-hour SO_2 concentration of 9.43 and 28.30 µg/m³ (for the locations of San Jose – Jackson St and Fresno – N First St, respectively) was added to the maximum increment off-site project contribution.
[8] A background 24-hour SO_2 concentration of 2.88 and 6.29 µg/m³ (for the locations of San Jose – Jackson St., Salinas – Laurel Dr, and Merced – S. Coffee, respectively) was added to the maximum increment off-site project contribution.
[9] "Combined" conservatively estimates the sum of worst-case concentrations from all features that can occur concurrently at one receptor location.
[10] Background concentration exceeds the AAQS.

CO = carbon monoxide
MOWF = maintenance of way facility
MOWS = maintenance of way siding
N/A = Not Applicable. Batch plants only have particulate matter emissions
NAAQS = national ambient air quality standards
NO_2 = nitrogen oxide
$PM_{2.5}$ = particulate matter 2.5 microns or less in diameter
PM_{10} = particulate matter 10 microns or less in diameter
SIL = significant impact level
µg/m³ = micrograms per cubic meter of air

[1] Only the highest modeled concentration in the form of the standard is presented for each pollutant. Values have been rounded. In some cases, the rounded value may appear to violate the ambient air quality standard. Only those results shown in underline with an asterisk (*) actually violate the standard.
[2] Represents the maximum incremental off-site concentration in the form of the standard from project construction.
[3] A background 1-hour CO concentration of 2,329, 2,215, and 3,475 µg/m³ (for the locations of San Jose – Jackson St., Salinas – Laurel Dr, and Madera – Rd. 29 1/2, respectively) was added to the maximum increment off-site project contribution.
[4] A background 8-hour CO concentration of 1,757, 992.85, and 1222 µg/m³ (for the locations of San Jose – Jackson St., Salinas – Laurel Dr, and Madera – Rd. 29 1/2, respectively) was added to the maximum increment off-site project contribution.
[5] A background 1-hour NO_2 concentration of 85.23, 49.51, and 61.41 µg/m³ (for the locations of San Jose – Jackson St., Salinas – Laurel Dr, and Merced – S. Coffee, respectively) was added to the maximum increment off-site project contribution.
[6] A background 24-hour $PM_{2.5}$ concentration in the form of the standard of 31.0, 14.67, and 39.33 µg/m³ (for the locations of San Jose – Jackson St., Hollister – Fairview Dr, and Merced – S. Coffee, respectively) was added to the maximum increment off-site project contribution.
[7] A background 24-hour PM_{10} concentration of 49.678, 56.33, and 73.33 µg/m³ (for the locations of San Jose – Jackson St., Hollister – Fairview Dr, and Merced – M St, respectively) was added to the maximum increment off-site project contribution.
[8] A background 1-hour SO_2 concentration of 6.11 and 15.72 µg/m³ (for the locations of San Jose – Jackson St and Fresno – N First St, respectively) was added to the maximum increment off-site project contribution.
[9] "Combined" conservatively estimates the sum of worst-case concentrations from all features that can occur concurrently at one receptor location.
[10] Background concentration exceeds the NAAQS. USEPA Office of Air Quality Planning and Standards, August, 2016.

CO = carbon monoxide
MOWF = maintenance of way facility
MOWS = maintenance of way siding
N/A = Not applicable. Batch plants only have particulate matter emissions
NAAQS = national ambient air quality standards
NO_2 = nitrogen oxide
$PM_{2.5}$ = particulate matter 2.5 microns or less in diameter
PM_{10} = particulate matter 10 microns or less in diameter
SIL = significant impact level
µg/m³ = micrograms per cubic meter of air

[1] Only the highest modeled concentration in the form of the standard is presented for each pollutant. Values have been rounded. In some cases, the rounded value may appear to violate the ambient air quality standard. Only those results shown in underline with an asterisk (*) actually violate the standard.
[2] Represents the maximum incremental off-site concentration in the form of the standard from project construction.
[3] A background 1-hour CO concentration of 2,329, 2,215, and 3,475 µg/m³ (for the locations of San Jose – Jackson St., Salinas – Laurel Dr, and Madera – Rd. 29 1/2, respectively) was added to the maximum increment off-site project contribution.
[4] A background 8-hour CO concentration of 1,757, 992.85, and 1222 µg/m³ (for the locations of San Jose – Jackson St., Salinas – Laurel Dr, and Madera – Rd. 29 1/2, respectively) was added to the maximum increment off-site project contribution.
[5] A background 1-hour NO_2 concentration of 85.23, 49.51, and 61.41 µg/m³ (for the locations of San Jose – Jackson St., Salinas – Laurel Dr, and Merced – S. Coffee, respectively) was added to the maximum increment off-site project contribution.
[6] A background 24-hour $PM_{2.5}$ concentration in the form of the standard of 31.0, 14.67, and 39.33 µg/m³ (for the locations of San Jose – Jackson St., Hollister – Fairview Dr, and Merced – S. Coffee, respectively) was added to the maximum increment off-site project contribution.
[7] A background 24-hour PM_{10} concentration of 49.678, 56.33, and 73.33 µg/m³ (for the locations of San Jose – Jackson St., Hollister – Fairview Dr, and Merced – M St, respectively) was added to the maximum increment off-site project contribution.
[8] A background 1-hour SO_2 concentration of 6.11 and 15.72 µg/m³ (for the locations of San Jose – Jackson St and Fresno – N First St, respectively) was added to the maximum increment off-site project contribution.
[9] "Combined" conservatively estimates the sum of worst-case concentrations from all features that can occur concurrently at one receptor location.
[10] Background concentration exceeds the NAAQS.

[3] A background annual NO_2 concentration in the form of the (CAAQS) standard of 24.08, 8.55 and 13.40 µg/m³ (for the locations of San Jose – Jackson St., Salinas – Laurel Dr, and Merced – S. Coffee, respectively) was added to the maximum increment off-site project contribution.
[4] A background annual NO_2 concentration in the form of the (NAAQS) standard of 23.75, 8.39 and 13.12 µg/m³ (for the locations of San Jose – Jackson St., Salinas – Laurel Dr, and Merced – S. Coffee, respectively) was added to the maximum increment off-site project contribution.
[5] A background annual $PM_{2.5}$ concentration in the form of the (CAAQS) standard of 10.60, 5.10 and 13.3 µg/m³ (for the locations of San Jose – Jackson St., Hollister - Fairview Dr, and Merced – S. Coffee, respectively) was added to the maximum increment off-site project contribution.
[6] A background annual $PM_{2.5}$ concentration in the form of the (NAAQS) standard of 9.57, 4.57 and 12.63 µg/m³ (for the locations of San Jose – Jackson St., Hollister - Fairview Dr, and Merced – S. Coffee, respectively) was added to the maximum increment off-site project contribution.
[7] A background annual PM_{10} concentration in the form of the (CAAQS) standard off 21.90, 19.6 and 35.8 µg/m³ (for the locations of San Jose – Jackson St., Hollister - Fairview Dr, and Merced – M St, respectively) was added to the maximum increment off-site project contribution.
[8] "Combined" conservatively estimates the sum of worst-case concentrations from all features that can occur concurrently at one receptor location.
[9] Background concentration exceeds the CAAQS and/or NAAQS.

This Page Intentionally Left Blank

7.12 Asbestos, Lead-Based Paint, Valley Fever, and Odors

7.12.1 Asbestos

NOA could become airborne as a result of excavating (including cuts and drilling deep foundations for aerial structures) or tunneling through ultramafic and metavolcanic bedrock. As noted in Section 6.5, Asbestos, Lead-Based Paint, Valley Fever, and Odors, no ultramafic or metavolcanic bedrock is mapped in the San Jose Diridon Station Approach or San Joaquin Valley Subsections. However, more than half of the alignment in the Pacheco Pass Subsection includes tunneling through bedrock that may contain zones of ultramafic or metavolcanic bedrock. Similarly, ultramafic rock is presented within the Monterey Corridor and Morgan Hill and Gilroy Subsections. While excavation and soil movement in these subsections may disturb NOA, the design-build contractor would prepare a CMP that outlines practices for avoiding and minimizing NOA. Construction contractors would also be required to comply with the BAAQMD's Asbestos Airborne Toxic Control Measure for Construction and Grading Operations, which requires implementation of dust control measures to limit the potential for airborne asbestos.

The demolition of asbestos-containing materials is subject to the limitations of the *National Emission Standards for Hazardous Air Pollutants* regulations and would require an asbestos inspection. The Authority would consult with the BAAQMD, MBARD, and SJVAPCD, as applicable, before demolition activities begin.

7.12.2 Lead-Based Paint

Buildings in the RSA might be contaminated with residual Pb, which was used as a pigment and drying agent in oil-based paint until the Lead-Based Paint Poisoning Prevention Act of 1971 prohibited such use. If encountered during demolitions and relocations for any of the project alternatives, LBP and asbestos would be handled and disposed of in accordance with applicable standards. Section 3.10, Hazardous Materials and Wastes, of the Final EIR/EIS discusses potential issues of LBP during construction of the project.

7.12.3 Valley Fever

While there are several factors that influence receptor exposure and development of Valley fever, earthmoving activities during construction could release C. immitis spores if filaments are present and other soil chemistry and climatic conditions are conducive to spore development. Receptors adjacent to the construction area may therefore be exposed to increased risk of inhaling C. immitis spores and subsequent development of Valley fever. Dust control measures are the primary defense against infection (USGS 2000). The project includes all best available fugitive dust control measures (see AQ-IAMF#1) that would avoid dusty conditions and reduce the risk of contracting Valley fever through routine watering and other measures.

7.12.4 Odors

Sources of odor during project construction would include diesel exhaust from construction equipment and asphalt paving. All odors would be localized and generally confined to the immediate area surrounding the construction site. The project would use typical construction techniques. The equipment odors would be temporary and localized, and they would cease once construction activities have been completed. The BAAQMD, MBARD, and SJVAPCD have adopted rules that limit the amount of ROG emissions from cutback asphalt (Section 3.3, Regional and Local).

No potentially odorous emissions would be associated with train operation because the trains would be powered from the regional electrical grid. There would be some area source emissions associated with station and maintenance facility operation, such as natural-gas combustion for space and water heating, landscaping equipment emissions, and minor solvent and paint use. The solvent and paint use could be odorous to sensitive receptors. However, the exposure would be less severe than the exposure to odors from other commercial and industrial activities that would occur in these areas under the No Project Alternative.

7.13 Summary of Effects

Project features, including IAMFs, design standards, and compliance with the Authority's project design guideline technical memoranda, would minimize effects of Air Quality. Table 7-52 summarizes the project alternatives' air quality effects.

Construction of all four project alternatives would result in ROG and NO_X emissions that would exceed the BAAQMD's CEQA thresholds, as well as the SJVAPCD's annual CEQA thresholds for NO_X, CO, and PM_{10}. Construction of all project alternatives would exceed the general conformity *de minimis* NO_X thresholds in the SFBAAB and SJVAB.

The project would be constructed with feasible on-site control measures to reduce emissions and minimize effects on air quality. Effects associated with fugitive dust emissions would be minimized through implementation of a dust control plan (AQ-IAMF#1) and best management practices at new concrete batch plants (AQ-IAMF#6). The contractor would use low-VOC paints to limit the emissions of VOCs (AQ-IAMF#2). Exhaust-related pollutants would be reduced through use of renewable diesel, Tier 4 off-road engines, and model year 2010 or newer on-road engines, as required by AQ-IAMF#3 through AQ-IAMF#5. However, even with application of IAMFs, exceedances of air district and general conformity thresholds would still occur.

The Authority would implement mitigation measures to reduce and offset the remaining construction impact on air quality resources. Specifically, AQ-MM#1 and AQ-MM#2 identify additional control strategies for reducing on-site emissions, including ZE or NZE requirements and goals for vehicles and off-road equipment. Remaining ROG and NO_X emissions after implementation of AQ-IAMF#1 through AQ-IAMF#6 and AQ-MM#1 and AQ-MM#2 would be offset in the BAAQMD to below BAAQMD thresholds or net zero (as required by the General Conformity regulation). ROG, NO_X, and PM emissions would be fully offset (i.e., to net zero) within the SJVAPCD, pursuant to the Authority's MOU with the air district for the HSR subsections within the SJVAB. Pursuant to SJVAPCD's GAMAQI, emissions offsets procured through AQ-MM#4 could not be used to mitigate CO effects. Accordingly, CO emissions would remain above SJVAPCD's CEQA threshold even after implementation of all feasible mitigation.

Construction activities would not exceed applicable local air district health risk thresholds or criteria; however, they would exceed state and federal ambient air quality standards. Construction of all alternatives would lead to new violations of the PM_{10} and $PM_{2.5}$ CAAQS and NAAQS, as well as potentially contribute to existing PM violations through exceedances of the SIL. Alternatives 1, 2, and 4 would also violate the 1-hour NO_2 NAAQS and CAAQS.

Table 7-52 Summary of Effects

Effect	Alternative 1	Alternative 2	Alternative 3	Alternative 4
Temporary Direct and Indirect Effects on Air Quality within the SFBAAB	Temporary construction activity would generate NO_X emissions in excess of the General Conformity *de minimis* threshold. Emissions would also exceed BAAQMD's ROG and NO_X CEQA thresholds.	Same as Alternative 1.	Same as Alternative 1.	Same as Alternative 1.

Effect	Alternative 1	Alternative 2	Alternative 3	Alternative 4
Temporary Direct and Indirect Effects on Air Quality within the NCCAB	Temporary construction activity would generate criteria pollutants, but those emissions would not exceed MBARD's PM_{10} threshold.	Same as Alternative 1.	Same as Alternative 1.	Same as Alternative 1.
Temporary Direct and Indirect Effects on Air Quality within the SJVAB	Temporary construction activity would generate NO_X emissions in excess of the General Conformity *de minimis* threshold. Emissions would also exceed SJVAPCD's NO_X, CO, and PM_{10} CEQA thresholds.	Same as Alternative 1.	Same as Alternative 1.	Same as Alternative 1.
Temporary Direct Effects on Implementation of an Applicable Air Quality Plan	Construction-related criteria pollutant emissions would exceed adopted air district thresholds in the BAAQMD and SJVAPCD, and the federal *de minimis* NOx thresholds in the SFBAAB and SJVAB.	Same as Alternative 1.	Same as Alternative 1.	Same as Alternative 1.
Temporary Direct Effects on Localized Air Quality—Criteria Pollutants	Temporary construction activity would violate the 1-hour NO_2 CAAQS and NAAQS, annual PM_{10} CAAQS, annual $PM_{2.5}$ CAAQS and NAAQS, and 24-hour $PM_{2.5}$ NAAQS. Emissions concentrations would also exceed the 24-hour and annual PM_{10} SIL and 24-hour and annual $PM_{2.5}$ SIL.	Same as Alternative 1.	Temporary construction activity would violate the annual PM_{10} CAAQS, annual $PM_{2.5}$ CAAQS and NAAQS, and 24-hour $PM_{2.5}$ NAAQS. Emissions concentrations would also exceed the 24-hour and annual PM_{10} SIL and 24-hour and annual $PM_{2.5}$ SIL.	Temporary construction activity would violate the 1-hour NO_2 CAAQS and NAAQS, annual and 24-hour PM_{10} CAAQS, annual $PM_{2.5}$ CAAQS and NAAQS, and 24-hour $PM_{2.5}$ NAAQS. Emissions concentrations would also exceed the 24-hour and annual PM_{10} SIL and 24-hour and annual $PM_{2.5}$ SIL.

Effect	Alternative 1	Alternative 2	Alternative 3	Alternative 4
Temporary Direct Effects on Localized Air Quality—Exposure to Diesel Particulate Matter and $PM_{2.5}$ (Health Risk)	Temporary construction activity would not generate DPM or $PM_{2.5}$ concentrations in excess of established health risk thresholds. The maximum increase in potential cancer risk (5.0 per million) would occur in the San Joaquin Valley Subsection.	Temporary construction activity would not generate DPM or $PM_{2.5}$ concentrations in excess of established health risk thresholds. The maximum increase in potential cancer risk (5.0 per million) would occur in the Monterey Corridor and San Joaquin Valley Subsections.	Temporary construction activity would not generate DPM or $PM_{2.5}$ concentrations in excess of established health risk thresholds. The maximum increase in potential cancer risk (9.4 per million) would occur in the Morgan Hill and Gilroy Subsection.	Temporary construction activity would not generate DPM or $PM_{2.5}$ concentrations in excess of established health risk thresholds. The maximum increase in potential cancer risk (6.1 per million) would occur in the Monterey Corridor Subsection.
Temporary Direct Effects on Localized Air Quality—Exposure to Asbestos, Lead-Based Paint, and Valley Fever	Project design and compliance with existing asbestos and LBP handling and disposal standards, as well as fugitive dust control practices, would prevent exposure of sensitive receptors to substantial pollutant concentrations. There would be limited potential for exposure of sensitive receptors to asbestos or LBP associated with demolition of 4.4 million square feet. There would be limited potential for exposure of sensitive receptors to Valley fever associated with movement of 51.5 million cubic yards of soil and disturbance of 813 acres.	Same as Alternative 1. There would be limited potential for exposure of sensitive receptors to asbestos or LBP associated with demolition of 6.3 million square feet. There would be limited potential for exposure of sensitive receptors to Valley fever associated with movement of 60.4 million cubic yards of soil and disturbance of 1,047 acres.	Same as Alternative 1. There would be limited potential for exposure of sensitive receptors to asbestos or LBP associated with demolition of 3.9 million square feet. There would be limited potential for exposure of sensitive receptors to Valley fever associated with movement of 58.7 million cubic yards of soil and disturbance of 870 acres.	Same as Alternative 1. There would be limited potential for exposure of sensitive receptors to asbestos or LBP associated with demolition of 2.2 million square feet. There would be limited potential for exposure of sensitive receptors to Valley fever associated with movement of 52.2 million cubic yards of soil and disturbance of 1,048 acres.
Temporary Direct Effects on Localized Air Quality—Exposure to Odors	There would be limited potential for odors generated by construction to affect sensitive receptors or result in nuisance complaints.	Same as Alternative 1.	Same as Alternative 1.	Same as Alternative 1.

Effect	Alternative 1	Alternative 2	Alternative 3	Alternative 4
Continuous Permanent Direct Effects on Air Quality within the SFBAAB, NCCAB, and SJVAB—On-Road Vehicle, Train, Aircraft, Station, and Maintenance Facility Emissions	Long-term operation of the HSR system would reduce criteria pollutant emissions, relative to No Project conditions, resulting in a regional and local air quality benefit. Annual reductions would range from 23 to 54 tons of VOC, 332 to 1,120 tons of CO, 208 to 447 tons of NO_X, 22 to 48 tons of SO_2, 25 to 69 tons of PM_{10}, and 11 to 26 tons of $PM_{2.5}$, depending on the ridership scenario.	Same as Alternative 1. Annual reductions would range from 23 to 54 tons of VOC, 332 to 1,120 tons of CO, 208 to 447 tons of NO_X, 22 to 48 tons of SO_2, 18 to 61 tons of PM_{10}, and 10 to 25 tons of $PM_{2.5}$, depending on the ridership scenario.	Same as Alternative 1. Annual reductions would range from 23 to 54 tons of VOC, 330 to 1,119 tons of CO, 208 to 447 tons of NO_X, 22 to 48 tons of SO_2, 23 to 66 tons of PM_{10}, and 10 to 26 tons of $PM_{2.5}$, depending on the ridership scenario.	Same as Alternative 1. Annual reductions would range from 23 to 54 tons of VOC, 332 to 1,120 tons of CO, 208 to 447 tons of NO_X, 22 to 48 tons of SO_2, 16 to 59 tons of PM_{10}, and 9 to 25 tons of $PM_{2.5}$, depending on the ridership scenario.
Continuous Permanent Direct Effects on Implementation of an Applicable Air Quality Plan	Emissions reductions from project operation would support implementation of air quality plans and attainment of regional air quality goals.	Same as Alternative 1.	Same as Alternative 1.	Same as Alternative 1.
Continuous Permanent Direct Effects on Localized Air Quality—Carbon Monoxide Hot Spots (NAAQS Compliance)	Increased project traffic would not result in localized CO hot spots or exceedances of the CO NAAQS or CAAQS.	Same as Alternative 1.	Same as Alternative 1.	Same as Alternative 1.
Continuous Permanent Direct Effects on Localized Air Quality—Exposure to Mobile Source Air Toxics	Operation of the HSR system would result in a regional MSAT reduction and benefit. Increased station traffic would have a low potential for meaningful localized MSAT impacts.	Same as Alternative 1.	Same as Alternative 1.	Same as Alternative 1.

Effect	Alternative 1	Alternative 2	Alternative 3	Alternative 4
Continuous Permanent Direct Effects on Localized Air Quality—Particulate Matter Hot Spots (NAAQS Compliance)	The project is not considered to be a project of air quality concern, based on the descriptions as indicated in 40 C.F.R. Section 93.123(b)(1).	Same as Alternative 1.	Same as Alternative 1.	Same as Alternative 1.
Continuous Permanent Direct Effects on Localized Air Quality—Exposure to Diesel Particulate Matter and $PM_{2.5}$ (Health Risk)	Emissions of DPM and $PM_{2.5}$ from relocated freight service and station and maintenance facility operation would not expose sensitive receptors to pollutant concentrations since health risks would not exceed BAAQMD's thresholds.	Same as Alternative 1.	Same as Alternative 1.	Same as Alternative 1.
Continuous Permanent Direct Effects on Localized Air Quality—Exposure to Odors	Emissions-generated odors would be limited and would not be expected to affect a substantial number of people.	Same as Alternative 1.	Same as Alternative 1.	Same as Alternative 1.

BAAQMD = Bay Area Air Quality Management District
C.F.R. = Code of Federal Regulations
CAAQS = California ambient air quality standards
CEQA = California Environmental Quality Act
CO = carbon monoxide
DPM = diesel particulate matter
HSR = high-speed rail
LBP = lead-based paint
MBARD = Monterey Bay Air Resources District
MSAT = mobile source air toxics
NAAQS = national ambient air quality standards
NCCAB = North Central Coast Air Basin
NO_2 = nitrogen dioxide
NO_X = nitrogen oxide
$PM_{2.5}$ = particulate matter 2.5 microns in diameter or less
PM_{10} = particulate matter 10 microns in diameter or less
ROG = reactive organic gas
SFBAAB = San Francisco Bay Area Air Basin
SIL = significant impact level
SJVAB = San Joaquin Valley Air Basin
SJVAPCD = San Joaquin Valley Air Pollution Control District
SO_2 = sulfur dioxide
VOC = volatile organic compound

8 GLOBAL CLIMATE CHANGE EFFECTS ANALYSIS

Using the methods described in Chapter 6, this chapter evaluates and discusses the effects of the project pertaining to global climate change and GHG.

8.1 Statewide and Regional Operations Emissions Analysis

Table 8-1 shows the statewide GHG emission changes (expressed in terms of CO_2e) that would result from the project under the medium and high ridership scenarios for the 2015 Existing and 2029 and 2040 No Project conditions. The analysis estimated the emission changes from reduced on-road VMT, reduced intrastate aircraft travel, and increased electrical demand. As Table 8-1 shows, the project is predicted to have a beneficial effect on statewide GHG emissions relative to both the 2015 Existing and 2029 and 2040 No Project conditions because it would result in a net reduction in GHG emissions. The estimated GHG emissions changes would be the same under all four project alternatives because the ridership scenarios do not vary by alternative. It should be noted that the emission savings due to reduced VMT are conservative because they do not consider the recently enacted SAFE Vehicles Rule. The SAFE Vehicles Rule increases GHG emission rates for light-duty gasoline-powered vehicles. As such, applying the SAFE Vehicles Rule would increase the benefits of the HSR VMT reductions by as much as 10 percent for CO_2 emissions in 2040 (CARB 2020).

This analysis considers the GHG effects associated with the project beyond 2020, consistent with SB 32 (Section 3.2.3.8, Senate Bill 32 and Assembly Bill 197), by assessing operations emissions for two conditions (2029 and 2040). Table 8-1 shows that the project would result in GHG reductions relative to the 2029 and 2040 No Project conditions and would help the state reach the goal established in SB 32 (40 percent below 1990 levels). Based on the 1990 emissions of 431 million metric tons CO_2e, the state would need to reduce emissions by 172 million metric tons CO_2e to achieve the SB 32 goal. The project would reduce statewide GHG emissions by 1.1–1.7 million metric tons CO_2e in the design year (2040), depending on the ridership scenario. These reductions correspond to an annual reduction of 0.6 to 1.0 percent of the 172 million metric tons CO_2e needed to achieve the SB 32 goal.

Table 8-1 Estimated Statewide Greenhouse Gas Emissions Change from the Project—Medium and High Ridership Scenarios (million metric tons CO_2e per year)

Emission Source	Change in CO_2e Emissions from HSR (million t/year)	
	Medium	High
Existing Plus Project Emissions Relative to 2015 Existing Conditions		
On-road vehicles	(1.1)	(1.5)
Aircraft	(0.7)	(0.7)
Power plants	0.4	0.4
Total statewide emissions	(1.4)	(1.8)
2029 Plus Project Emissions Relative to 2029 No Project Conditions		
On-road vehicles	(0.4)	(0.3)
Aircraft	(0.5)	(0.5)
Power plants	0.3	0.3
Total statewide emissions	(0.6)	(0.4)

Emission Source	Change in CO_2e Emissions from HSR (million t/year)	
	Medium	High
2040 Plus Project Emissions Relative to 2040 No Project Conditions		
On-road vehicles	(0.5)	(1.1)
Aircraft	(1.0)	(0.9)
Power plants	0.4	0.4
Total statewide emissions	(1.1)	(1.7)

Source: Authority 2020
(Parentheses) indicate negative values
Totals may not add up exactly because of rounding.
CO_2e = carbon dioxide equivalent
HSR = high-speed rail
t = metric tons

Table 8-1 also shows that the net change in emissions for 2015 Existing conditions would be a decrease in GHG emissions. Despite increases in power plant emissions from the project plus all other statewide activity between 2015 and 2040, total statewide GHG emissions in 2040 would be less than the level of GHG emissions in 2015. As evident in Table 8-1, the primary factor for the net decrease in emissions is decreases in on-road vehicle emissions related to advancements in vehicle emissions technology and the retirement of older, higher-emitting vehicles. Statewide growth would increase background aircraft emissions, but the project would reduce emissions relative to the No Project conditions by diverting passengers from aircraft to HSR. Therefore, the project's effect on GHG emissions would be beneficial with respect to both 2015 Existing conditions and the 2029 and 2040 No Project conditions.

8.1.1 On-Road Vehicles

The project would reduce annual roadway VMT compared to 2015 Existing Conditions and the 2029 and 2040 No Project conditions because travelers would use the HSR rather than drive (see Table 7-6 for VMT under No Project and Plus Project conditions). The on-road vehicle emission analysis is based on projected VMT changes and associated average daily speed estimates, calculated based on the ridership estimates presented in the 2016 Business Plan (Authority 2016). Analysts obtained GHG emission factors from EMFAC2017, using statewide parameters.

As shown in Table 8-2, the project is predicted to decrease statewide on-road GHG emissions relative to both 2015 Existing conditions and 2029 and 2040 No Project conditions. On county and regional levels, Table 8-2 also shows the project is predicted to result in a decrease in on-road GHG emissions relative to both conditions, as well. As discussed previously, on-road vehicle emissions are expected to decrease in the future because of advancements in vehicle emissions technology and the retirement of older, higher-emitting vehicles. Therefore, the reduction in GHG emissions from on-road vehicles because of the project is demonstrated on the county, regional, and statewide levels for both conditions. The change in emissions would be the same under all four project alternatives because the ridership is assumed to be the same. As noted above, the mobile source emissions reductions shown in Table 8-2 are conservative because they do not account for the SAFE Vehicles Rule, which will increase GHG emissions (and thus the benefits of the HSR VMT reductions) generated by light-duty gasoline-powered vehicles.

Table 8-2 Regional On-Road Vehicle Greenhouse Gas Emission Changes from the Project—Medium and High Ridership Scenarios (million metric tons CO_2e per year)

Location	Change in CO_2e Emissions from HSR (million t/year)	
	Medium	High
Existing Plus Project Emissions Relative to 2015 Existing Conditions

Totals may not add up exactly because of rounding.
CO_2e = carbon dioxide equivalent
t = metric tons
HSR = high-speed rail

8.1.2 Trains

The project would use EMU trains, with the power distributed through the overhead contact system. The HSR system would not produce direct GHG emissions from combustion of fossil fuels and associated emissions. Electricity-related emissions are assessed in Section 8.1.4, Power Plants.

8.1.3 Aircraft

As described in Section 6.2.3, analysts calculated aircraft emissions by using fuel consumption and emission factors, profiles of aircrafts, and number of air trips removed. Refer to Table 7-10 for the number of flights in 2015, 2029, and 2040 with and without the project. As shown in Table 8-3, the project would reduce regional (Bay Area) and statewide emissions relative to 2015 Existing and 2029 and 2040 No Project conditions. The change in emissions would be the same under all four project alternatives because the ridership is assumed to be the same.

Table 8-3 Aircraft Greenhouse Gas Emission Changes from the Project—Medium and High Ridership Scenarios (million metric tons CO_2e per year)

Location	Change in CO_2e Emissions from HSR (million t/year)	
	Medium	High
Existing Plus Project Emissions Relative to 2015 Existing Conditions

(Parentheses) indicate negative values
Totals may not add up exactly because of rounding.
CO_2e = carbon dioxide equivalent
HSR = high-speed rail
t = metric tons

8.1.4 Power Plants

The HSR system would increase electrical requirements when compared to both the 2015 Existing and 2029 and 2040 No Project conditions. Analysts conservatively estimated the electrical demands from propulsion of the trains and operation of the trains in storage depots and maintenance facilities. Table 8-4 shows the GHG emissions for both medium and high ridership scenarios relative to the 2015 Existing Conditions and 2029 and 2040 No Project conditions. Emissions would increase under both scenarios.

The state's electrical grid would power the HSR system, and, therefore, no single generation source for the electrical power requirements can be identified. As previously discussed, the state requires an increasing fraction (60 percent by 2030) of electricity generated for the state's power portfolio to come from renewable energy sources, and the Authority has a policy goal to use 100 percent renewable energy to power the HSR system. Accordingly, the GHG emissions generated for powering the HSR system are expected to be lower in the future compared to emission estimates used in this analysis, which assume the current energy mix of California. As shown in Table 8-4, the HSR system's electrical requirements would increase statewide and regional indirect GHG emissions.

Table 8-4 Power Plant Greenhouse Gas Emission Changes from the Project—Medium and High Ridership Scenarios (million metric tons CO_2e per year)

Location	Change in CO_2e Emissions from HSR (million t/year)	
	Medium	High

8.1.5 Regional Operations Greenhouse Gas Emissions Summary

A summary of the effects of the project on regional GHG emissions, which include the emissions from vehicles, aircraft, and power plants, is shown in Table 8-5. The project would reduce regional GHG emissions relative to 2015 Existing and 2029 and 2040 No Project conditions. However, this regional assessment does not account for the benefit of emissions reductions in roadway and airplane emissions that would occur statewide. Likewise, as noted above, emission savings shown in Table 8-5 due to reduced VMT do not consider the recently enacted SAFE Vehicles Rule. The SAFE Vehicles Rule increases GHG emission rates for light-duty gasoline-powered vehicles. As such, applying the SAFE Vehicles Rule would increase the benefits of the HSR VMT reductions by as much as 10 percent for CO_2 in 2040 (CARB 2020). Therefore, the full benefit of the project is not reflected in the emissions at the regional level. However, as shown in Table 8-5, the project would result in a net reduction in GHG emissions statewide for both conditions. Because GHGs circulate globally, an increase at the regional level would not be adverse, given the net reduction at the state level. There would be no difference in emissions among the alternatives because ridership is assumed to be the same.

Table 8-5 Estimated Regional Greenhouse Gas Emissions Change from the Project—Medium and High Ridership Scenarios (million metric tons CO_2e per year)

Emission Source	Change in CO_2e Emissions from HSR (million t/year)	
	Medium	High
Existing Plus Project Emissions Relative to 2015 Existing Conditions		
On-road vehicles	(0.1)	(0.2)
Aircraft	(0.3)	(0.3)

8.2 Local Operations Emissions Sources

Operation of the San Jose Diridon and Gilroy stations and maintenance facilities would produce GHG emissions. Likewise, additional circuit breakers installed as part of the PG&E reconductoring work may result in fugitive SF_6 emissions. The operation of the power traction, switching, and paralleling stations would not result in appreciable quantities of air pollutants because site visits would be infrequent, and power usage would be limited. Therefore, analysts did not quantify emissions from these stations. This section therefore focuses on emissions generated by the station sites, maintenance facilities, and SF_6 circuit breakers.

8.2.1 Station Sites and Maintenance Facilities

Emissions associated with the operation of stations and maintenance facilities are expected because of combustion sources used primarily for space heating and facility landscaping, energy consumption for facility lighting, water usage, waste generation, and employee and passenger traffic. Analysts used CalEEMod to estimate these emissions from the stations and maintenance facilities, based on the square footage of the buildings. Mobile source emissions estimates were adjusted to reflect the impact of the SAFE Vehicles Rule (CARB 2020). Operation of the MOWF would also generate emissions from vehicles, equipment, and locomotives used for maintenance activities. The GHG emissions (expressed in terms of CO_2e) were estimated for the 2015 Existing and 2029 and 2040 No Project conditions and are included in Table 8-6. The only difference in emissions among the alternatives is associated with the Gilroy stations. Since the East Gilroy Station is entirely new, net emissions are greater than the Downtown Gilroy Station since emissions under existing conditions are zero.

Table 8-6 Station and Maintenance Facility Operational Greenhouse Gas Emissions (metric tons CO_2e per year)

Project Component	CO_2e
2015 Existing[1]	
San Jose Diridon Station	2,780
Downtown Gilroy Station	234
Existing Plus Project	
San Jose Diridon Station[3]	4,934
Downtown Gilroy Station[4]	3,180
East Gilroy Station	3,148

Project Component	CO_2e
MOWF[5]	3,861
MOWS	2,144
PROJECT CHANGE – Alternatives 1, 2, and 4	**11,106**
PROJECT CHANGE – Alternative 3	**11,308**
2029 No Project[1]	
San Jose Diridon Station	2,510
Downtown Gilroy Station	218
2029 Plus Project	
San Jose Diridon Station[3]	3,870
Downtown Gilroy Station[4]	2,636
East Gilroy Station	3,166
MOWF[5]	3,416
MOWS	1,897
PROJECT CHANGE – Alternatives 1, 2, and 4	**9,090**
PROJECT CHANGE – Alternative 3	**9,838**
2040 No Project[1]	
San Jose Diridon Station	2,799
Downtown Gilroy Station	240
2040 Plus Project	
San Jose Diridon Station[3]	6,676
Downtown Gilroy Station[4]	4,752
East Gilroy Station	5,295
MOWF[5]	3,348
MOWS	1,932
PROJECT CHANGE – Alternatives 1, 2, and 4	**13,669**
PROJECT CHANGE – Alternative 3	**14,452**

Sources: Trinity Consultants 2016; Newson 2018; USEPA 2009; Burton 2017a, 2017b, 2017c, 2018 ; McGuire 2017–2018
CO_2e = carbon dioxide equivalent
MOWF = maintenance of way facility
MOWS = maintenance of way siting
[1] Represents emissions from the existing facilities prior to HSR improvements. The East Gilroy Station, MOWF, and MOWS do not exist under existing conditions, and, as such, existing emissions are assumed to be zero.
[2] There would be no difference in operational emissions between the aerial and at-grade options.
[3] There would be no difference in operational emissions between the aerial and embankment options.
[4] There would be no difference in operational emissions between the south and east Gilroy options.

8.2.2 Sulfur Hexafluoride Circuit Breakers

PG&E substations and switching stations would require the installation of electrical equipment, including up to 12 power circuit breakers with SF_6 gas-type insulated switchgear. It is assumed that the annual SF_6 leakage rates associated with the 12 additional circuit breakers (up to 230 pounds each) would not exceed 0.5 percent. Based on the GWP of SF_6 (see Section 4.4,

Greenhouse Gases), the additional equipment would result in approximately 143 metric tons of CO_2e emissions annually for all four project alternatives.

8.3 Total Operations Emissions

Table 8-7 shows the total GHG emission changes because of project operation for the medium and high ridership scenarios, including the indirect emissions from regional vehicle travel, aircraft, and power plants and direct project operations emissions from HSR stations, maintenance facilities, and SF_6 circuit breakers under the project. The project would result in a net decrease in GHG emissions. These decreases would be beneficial to the SFBAAB, NCCAB, SJVAB, and state and would help meet local and statewide GHG reduction goals. Although lower ridership would result, there would still be a net benefit. The overall change in GHG emissions would be approximately the same under all four project alternatives. As noted above, the emission savings due to reduced VMT are conservative because they do not consider the recently enacted SAFE Vehicles Rule. The SAFE Vehicles Rule increases GHG emission rates for light-duty gasoline-powered vehicles. As such, applying the SAFE Vehicles Rule would increase the benefits of the HSR VMT reductions by as much as 10 percent for CO_2 emissions in 2040 (CARB 2020).

Table 8-7 Summary of Total Statewide Greenhouse Gas Emissions Changes from Operation of the Project—2015 Existing and 2029 and 2040 No Project Conditions (Medium and High Ridership Scenarios) (million metric tons CO_2e per year)

Emission Source	Change in CO_2e Emissions from HSR (Million t/year)	
	Medium	High

(Parentheses) indicate negative values
CO_2e = carbon dioxide equivalent
HSR = high-speed rail
t = metric tons
SF_6 = sulfur hexafluoride
[1] Sum of station, maintenance facility, and SF_6 circuit breaker emissions. Represents the net emissions effect of the project (i.e., the difference in operating emissions between existing or No Project condition and the project condition).
[2] The total includes the indirect and direct emissions for the alternative (Alternative 3) with the greatest total emissions. Totals may not add up exactly because of rounding.

8.4 Construction Greenhouse Gas Emissions

GHG emissions generated from construction of the project would be short term. However, since the time that CO_2 remains in the atmosphere cannot be definitively quantified because of the wide range of time scales in which carbon reservoirs exchange CO_2 with the atmosphere, there is no single value for the half-life of CO_2 in the atmosphere (IPCC 2007). Therefore, the duration that CO_2 emissions from a short-term project would remain in the atmosphere is unknown.

Tables 8-8 through 8-11 show construction activity emissions from the project. The analysis reflects the impact of the SAFE Vehicles Rule (CARB 2020) and assumes implementation of AQ-IAMF#1 through AQ-IAMF#6. However, because the penetration of ZE and NZE off-road equipment and heavy-duty vehicles in future construction fleets is unknown, emissions reductions achieved by AQ-MM#2 cannot currently be quantified or included in the analysis. The total GHG construction emissions of the project (Alternative 4) would be less than 0.15 percent of the total annual statewide GHG emissions.[29]

Tables 8-8 through 8-10 also show the amortized GHG emissions during project construction activities. GHG pollutants such as N_2O can remain in the atmosphere for 120 years (IPCC 2007). A 25-year project life is conservatively assumed (although the actual project life would be much longer). Total amortized GHG construction emissions for the project are estimated to be between

[29] A GHG emissions inventory for the regional project vicinity was not available at the time of the release of this document, so the comparison was made to CARB's 2016 emissions inventory, which estimated that the annual CO_2e emissions in California are about 429 million metric tons (CARB 2018d).

14,870 and 20,043 metric tons CO_2e per year, with Alternative 4 generating the most emissions, and Alternative 1 generating the least. Most emissions would occur in the BAAQMD (58 percent to 65 percent), followed by SJVAPCD (28 percent to 37 percent), and MBARD (4 percent to 7 percent). The increase in GHG emissions generated during construction would be offset in 8 to 14 months, depending on the alternative, during operation by the net GHG reductions in operation (because of car and aircraft trips removed in the RSA), relative to No Project conditions.

Table 8-8 Alternative 1 Carbon Dioxide Equivalent Construction Emissions (metric tons per year)[1, 2]

Year	Air District		
	BAAQMD	MBARD	SJVAPCD
2022	30,032	4,662	14,621
2023	47,001	3,274	28,274
2024	59,992	2,647	28,581
2025	45,788	2,118	25,893
2026	20,596	1,201	22,709
2027	11,084	1,217	17,495
2028	2,352	279	1,935
Total by air district	216,845	15,399	139,508
Construction total	371,752		
Amortized GHG Emissions (averaged over 25 years)			
CO_2e per year by air district	8,674	616	5,580
CO_2e per year for total construction	14,870		
Payback of GHG Emissions (months)[2, 3]			
Payback period (project vs. 2029 no project)	8 to 10

BAAQMD = Bay Area Air Quality Management District
CO_2e = carbon dioxide equivalent
GHG = greenhouse gas
MBARD = Monterey Bay Air Resources District
SJVAPCD = San Joaquin Valley Air Pollution Control District
< = less than
[1] Project life assumed to be 25 years.
[2] Payback periods were estimated by dividing the GHG emissions during construction by the annual GHG emission reduction during operation. See Table 8-7 for operational GHG emission-reduction data. The range in payback days represents the range of emissions changes based on the medium and high ridership scenarios.
[3] The payback period accounts for all emissions directly and indirectly generated by construction activities for which the Authority has practical control and program responsibility. Emissions generated upstream (e.g., material manufacturing) and downstream (e.g., recycling) of construction, otherwise known as "lifecycle emissions", are not included in the analysis, consistent with guidance from the California Natural Resources Agency (2018). While the origin of most raw materials is not known, and thus an emissions analysis would be speculative, construction of the project would require concrete from on- and off-site batch plants. Lifecycle emissions for cement and aggregate manufacturing, which is upstream of the concrete batching process, have been studied in various literature. Accordingly, for the purposes of disclosure, analysts quantified upstream CO_2 emissions resulting from cement and aggregate manufacturing using emission factors from Marceau et al. (2007). It was assumed the tunnel segments would require a compression strength of 7,500 pounds per square inch and all other infrastructure would require a compression strength of 5,000 pounds per square inch. The analysis indicates that cement and aggregate manufacturing would generate 1,004,663 metric tons CO_2e. These emissions would be generated upstream of construction and through activities for which the Authority has no practical control. The emissions are therefore disclosed for informational purposes only. Nonetheless, it is worth noting that if the emissions were added to the 371,752 metric tons CO_2e generated by construction of Alternative 1, the combined total emissions would be offset in 2 to 3 years (relative to 2029 No Project conditions).

Table 8-9 Alternative 2 Carbon Dioxide Equivalent Construction Emissions (metric tons per year)[1, 2]

Year	Air District

[1] Project life assumed to be 25 years.
[2] Payback periods were estimated by dividing the GHG emissions during construction by the annual GHG emission reduction during operation. See Table 8-7 for operational GHG emission-reduction data. The range in payback days represents the range of emissions changes based on the medium and high ridership scenarios.
[3] The payback period accounts for all emissions directly and indirectly generated by construction activities for which the Authority has practical control and program responsibility. Emissions generated upstream (e.g., material manufacturing) and downstream (e.g., recycling) of construction, otherwise known as "lifecycle emissions", are not included in the analysis, consistent with guidance from the California Natural Resources Agency (2018). While the origin of most raw materials is not known, and thus an emissions analysis would be speculative, construction of the project would require concrete from on- and off-site batch plants. Lifecycle emissions for cement and aggregate manufacturing, which is upstream of the concrete batching process, have been studied in various literature. Accordingly, for the purposes of disclosure, analysts quantified upstream CO_2 emissions resulting from cement and aggregate manufacturing using emission factors from Marceau et al. (2007). It was assumed the tunnel segments would require a compression strength of 7,500 pounds per square inch and all other infrastructure would require a compression strength of 5,000 pounds per square inch. The analysis indicates that cement and aggregate manufacturing would generate 1,040,538 metric tons CO_2e. These emissions would be generated upstream of construction and through activities for which the Authority has no practical control. The emissions are therefore disclosed for informational purposes only. Nonetheless, it is worth noting that if the emissions were added to the 465,635 metric tons CO_2e generated by construction of Alternative 2, the combined total emissions would be offset in about 3 years (relative to 2029 No Project conditions).

[3] The payback period accounts for all emissions directly and indirectly generated by construction activities for which the Authority has practical control and program responsibility. Emissions generated upstream (e.g., material manufacturing) and downstream (e.g., recycling) of construction, otherwise known as "lifecycle emissions", are not included in the analysis, consistent with guidance from the California Natural Resources Agency (2018). While the origin of most raw materials is not known, and thus an emissions analysis would be speculative, construction of the project would require concrete from on- and off-site batch plants. Lifecycle emissions for cement and aggregate manufacturing, which is upstream of the concrete batching process, have been studied in various literature. Accordingly, for the purposes of disclosure, analysts quantified upstream CO_2 emissions resulting from cement and aggregate manufacturing using emission factors from Marceau et al. (2007). It was assumed the tunnel segments would require a compression strength of 7,500 pounds per square inch and all other infrastructure would require a compression strength of 5,000 pounds per square inch. The analysis indicates that cement and aggregate manufacturing would generate 925,308 metric tons CO_2e. These emissions would be generated upstream of construction and through activities for which the Authority has no practical control. The emissions are therefore disclosed for informational purposes only. Nonetheless, it is worth noting that if the emissions were added to the 501,070 metric tons CO_2e generated by construction of Alternative 4, the combined total emissions would be offset in 2 to 3 years (relative to 2029 No Project conditions).

8.5 Summary of Effects

Project features, including IAMFs, design standards, and compliance with the Authority's project design guideline technical memoranda, would avoid or minimize effects of GHGs. Table 8-12 summarizes the project's effects associated with GHG by alternative. The project would lower GHG emissions overall.

Table 8-12 Summary of Effects

Impacts	Alternative 1	Alternative 2	Alternative 3	Alternative 4
Temporary Direct and Indirect Effects on Global Climate Change—Greenhouse Gas Emissions	GHG emissions generated during temporary construction of 14,870 t CO_2e per year would be offset by reductions achieved through project operation in 8 to 10 months (relative to 2029 No Project conditions).	GHG emissions generated during temporary construction of 18,635 t CO_2e per year would be offset by reductions achieved through project operation in 9 to 13 months (relative to 2029 No Project conditions).	GHG emissions generated during temporary construction of 15,082 t CO_2e per year would be offset by reductions achieved through project operation in 8 to 10 months (relative to 2029 No Project conditions).	GHG emissions generated during temporary construction of 20,043 t CO_2e per year would be offset by reductions achieved through project operation in 10 to 14 months (relative to 2029 No Project conditions).
Continuous Permanent Direct and Indirect Effects on Global Climate Change—Greenhouse Gas Emissions	Long-term operation of the HSR system would reduce GHG emissions, relative to No Project conditions, resulting in a statewide and regional GHG benefit. Annual reductions would range from 1.1 million mt CO_2e to 1.6 million mt CO_2e, depending on the ridership scenario.	Same as Alternative 1.	Same as Alternative 1.	Same as Alternative 1.

GHG = greenhouse gas
t = metric tons

9 MITIGATION MEASURES

This chapter presents mitigation measures the Authority would implement to address effects on air quality.

AQ-MM#1: Implement Additional On-Site Emissions Controls to Reduce Fugitive Dust

During construction, the Contractor shall employ the following measures to minimize and control fugitive dust emissions:

- Where feasible, install wind breaks (e.g., dust curtains, plastic tarps, solid fencing) on the average dominant windward side(s) of construction areas. For purposes of implementation, chain-link fencing with added landscape mesh fabric adequately qualifies as solid fencing.
- Post a publicly visible sign with the telephone number and person to contact at the Authority regarding dust complaints. This person shall respond and take corrective action within 48 hours. The phone number for the local air district shall also be visible to ensure compliance with applicable regulations.

AQ-MM#2: Construction Emissions Reductions – Requirements for Use of Zero Emission (ZE) and/or Near Zero Emission (NZE) Vehicles and Off-Road Equipment

This mitigation measure will reduce the impact of construction emissions from project related on-road vehicles and off-road equipment.

The Authority and all project construction contractors shall require that a minimum of 25 percent, with a goal of 100 percent, of all light-duty on-road vehicles (e.g., passenger cars, light-duty trucks) associated with the project (e.g., on-site vehicles, contractor vehicles) use ZE or NZE technology.

The Authority and all project construction contractors shall have the goal that a minimum of 25 percent of all heavy-duty on-road vehicles (e.g., for hauling, material delivery and soil import/export) associated with the project use ZE or NZE technology.

The Authority and all project construction contractors shall have the goal that a minimum of 10 percent of off-road construction equipment use ZE or NZE vehicles.

If local or state regulations mandate a faster transition to using ZE and/or NZE vehicles at the time of construction, the more stringent regulations will be applied. For example, EO N-79-20, issued by California Governor Newsom September 23, 2020, currently states the following:

- Light duty and passenger car sales be 100 percent ZE vehicles by 2035
- Full transition to ZE short haul/drayage trucks by 2035
- Full transition to ZE heavy-duty long-haul trucks, where feasible, by 2045
- Full transition to ZE off-road equipment by 2035, where feasible.

The project will have a goal of surpassing the requirements of these or other future regulations as a mitigation measure.

AQ-MM#3: Offset Project Construction Emissions in the San Francisco Bay Area Air Basin

Prior to issuance of construction contracts, the Authority will conduct an air quality analysis that evaluates the conditions that exist at that time. If the analysis determines that there will be exceedances of the VOC or NOx thresholds, even after the application of the mitigation in AQ-MM#2, the Authority will enter into an agreement with BAAQMD to reduce VOC and NO_X to the required levels by acquiring offsets. The required levels in the SFBAAB are as follows:

1. For emissions in excess of the General Conformity *de minimis* thresholds (NO_X): net zero.
2. For emissions not in excess of *de minimis* thresholds but above the BAAQMD's daily emission thresholds (VOC and NO_X): below the appropriate CEQA threshold levels.

The mitigation offset fee amount will be determined at the time of mitigation to fund one or more emissions reduction projects within the SFBAAB. The offset fee will be determined by the Authority and BAAQMD based on the type of projects that present appropriate emission reduction opportunities. These funds may be spent to reduce either VOC or NO_X emissions ("O_3 precursors"). Documentation of payment will be provided to the Authority or its designated representative.

The agreement will include details regarding the annual calculation of required offsets the Authority must achieve, funds to be paid, administrative fee, and the timing of the emissions reductions projects. Acceptance of this fee by BAAQMD will serve as an acknowledgment and commitment by BAAQMD to: (1) implement an emissions reduction project(s) within a timeframe to be determined based on the type of project(s) selected after receipt of the mitigation fee designed to achieve the emission reduction objectives; and (2) provide documentation to the Authority or its designated representative describing the project(s) funded by the mitigation fee, including the amount of emissions reduced (tons per year) in the SFBAAB from the emissions reduction project(s). To qualify under this mitigation measure, the specific emissions reduction project(s) must result in emission reductions in the SFBAAB that are real, surplus, quantifiable, enforceable, and will not otherwise be achieved through compliance with existing regulatory requirements or any other legal requirement. Pursuant to 40 C.F.R. Section 93.163(a), the necessary reductions must be achieved (contracted and delivered) by the applicable year in question. Funding will need to be received by BAAQMD prior to contracting with participants and should allow enough time to receive and process applications to fund and implement off-site reduction projects prior to commencement of project activities being reduced. This will roughly equate to 1 year prior to the required mitigation; additional lead time may be necessary depending on the level of off-site emission reductions required for a specific year.

This mitigation measure will be effective in offsetting emissions generated during project construction through the funding of emission-reduction projects. It is BAAQMD's experience that emissions offsets are feasible mitigation that effectively achieves actual emission reductions (Kirk 2018).

The implementation of this mitigation measure will not be expected to affect air quality in the BAAQMD because purchasing emissions offsets will not result in any physical change to the environment, and therefore will not result in other secondary environmental impacts. In addition to VOC and NO_X, the implementation of emission-reduction projects could result in reductions of other criteria pollutants and/or GHGs. However, this will be a secondary effect of this mitigation measure and is not a required outcome to mitigate any impacts of the project.

AQ-MM#4: Offset Project Construction Emissions in the San Joaquin Valley Air Basin

On June 19, 2014, the SJVAPCD and Authority entered a Memorandum of Understanding (MOU) that establishes the framework for fully mitigating to net zero construction emissions of NOx, VOC, PM_{10}, and $PM_{2.5}$ from the entire High-Speed Rail Project within the SJVAB (Authority and SJVUAPCD 2014). Emissions generated by construction of the portion of the project within the SJVAB are subject to this MOU and therefore must be offset to net zero. Pursuant to the MOU, the Authority and the SJVAPCD will enter into a Voluntary Emissions Reduction Agreement (VERA) to cover the portion of the project approved and funded for construction within the SJVAB. The project-level VERA must be executed prior to commencement of construction and the mitigation fees and offsets delivered and achieved according to the requirements of the VERA and MOU.

This mitigation measure will be effective in offsetting emissions generated during construction of the project through the funding of emission-reduction projects. It is SJVAPCD's experience that implementation of a VERA is feasible mitigation that effectively achieves actual emission reductions. Based on the performance of current incentive programs and reasonably foreseeable future growth, the SJVAPCD has confirmed that enough emissions reduction credits will be available to offset emissions generated by the project for all years in excess of the SJVAPCD's thresholds and the General Conformity *de minimis* threshold (Authority and SJVUAPCD 2014).

The implementation of this mitigation measure will not be expected to affect air quality in the SJVAPCD because purchasing emissions offsets will not result in any physical change to the environment, and therefore will not result in other secondary environmental impacts. In addition to NO_X and PM_{10}, the implementation of emission-reduction projects could result in reductions of other criteria pollutants, GHGs, or both. However, this will be a secondary effect of this mitigation measure and is not a required outcome to mitigate any impacts of the project.

This Page Intentionally Left Blank

10 CUMULATIVE EFFECTS

The RSA for cumulative air quality is the SFBAAB, NCCAB, and SJVAB, and the RSA for global climate change is the state and global atmosphere. Air quality and global climate change are inherently cumulative resources because criteria pollutant and GHG emissions, once emitted, mix into the atmosphere and affect a larger area than an individual project site. Thus, this cumulative analysis does not consider individual cumulative projects near the project; rather, it uses the same thresholds of significance as the project-level analysis (except for health risks in BAAQMD) because of the inherently cumulative nature of these resources.

10.1 Near- and Long-Term Operations

State: Even with the more stringent regulations on GHG emissions expected in the future, projected growth in California may result in cumulative increases in GHG emissions. Increased GHG emissions from past, present, and reasonably foreseeable future projects in the state would result in effects on global climate change. The project's statewide demand for electricity could result in indirect GHG emissions from power generation facilities. Although the Authority has adopted a policy to purchase renewable, clean-power energy sources, it cannot guarantee that only renewable energy is used to power the HSR system because the local power distribution network does not distribute energy based on energy sources. Therefore, GHG emissions may be associated with the provisions of energy to the HSR system. However, the project would decrease overall GHG emissions by reducing vehicle and aircraft trips and would also result in a net reduction in CO_2 emissions, as described in Chapter 8. Global Climate Change Effects Analysis. This reduction in GHG emissions would more than offset the increase in GHG emissions associated with project facilities. Therefore, the project would result in a net decrease in GHG emissions from operations.

Regional: Operation of the HSR system would help the region attain air quality standards and plans by reducing the amount of regional vehicular traffic and providing an alternative mode of transportation. Because the project would help to decrease emissions of criteria pollutants and precursors (e.g., ROG, NO_X), it would result in a net benefit to regional air quality.

Local: Cumulative CO effects would not occur because, as discussed in Section 7.5, Microscale Carbon Monoxide Hot-Spot Analysis, additional traffic created by the project would not result in CO concentrations in excess of the NAAQS or CAAQS.

Multiple sources of cumulative (existing sources and future planned) TAC emissions are located within 1,000 feet of the relocated freight sections and HSR stations, including the following:

- **Existing sources**—Multiple stationary, rail, and roadway sources are currently located along the alignment.
- **Planned land use development**—Land use development in the region would increase traffic levels and result in increased vehicle-related emissions along roadways, although, over time, state and federal regulations would reduce the allowed emission rates for new vehicles. Planned development may also generate additional DPM from emergency generators and truck loading bays, as well as DPM during construction of near-term improvements.
- **Future passenger service expansion**—There are proposals to expand passenger train service from the Transportation Agency for Monterey County (TAMC) to extend rail service from Salinas to Gilroy, from the Capitol Corridor Joint Powers Authority to expand existing service between San Jose and Sacramento, and from the San Joaquin Regional Rail Commission to expand existing Altamont Corridor Express (ACE) service from Stockton and Merced to San Jose. In addition, Facebook and San Mateo Transit District are exploring Dumbarton Rail Corridor service, which in the past has included potential service from the East Bay to San Jose and there have been proposals to add Coast Daylight service from Los Angeles to San Francisco. TAMC's Monterey County Rail Extension project has completed environmental review and is funded to start initial service. Environmental compliance for improvements necessary to facilitate expanded Capitol Corridor, ACE, or Dumbarton Rail service to San Jose has not been completed and funding has not yet been obtained, so they

are not included in the cumulative analysis. Plans and funding for the Coast Daylight service are uncertain, so it has not been included in the cumulative analysis.

- **Freight rail service expansion**—Freight rail service may also expand in the future as the economy expands. The exact amount of freight rail transport is difficult to predict. Freight levels depend on not only the overall level of economic activity but also the specific demand for bulk and oversize commodities that dominate freight carried by rail. As a conservative assessment, analysts assumed that freight would increase in the future at a rate of 3.5 percent per annum (PCJPB 2015) rounded up to 4 percent. This rate is an informal rate that freight operators, such as UPRR, often cite.

A quantitative HRA has not been conducted to estimate future DPM-related health risks to nearby sensitive receptors from cumulative land use development because construction and operations details are not available, and those projects would be responsible for analyzing their contributions. The cumulative HRA, therefore, focuses on ambient concentrations from stationary, rail, and roadway sources.

The BAAQMD has developed Google Earth and geographic information system (GIS) raster files that identify source-specific health risks throughout the SFBAAB. Analysts used these files to screen the relocated freight alignment and select one area per section to analyze cumulative health risks. The selected areas were chosen based on their proximity to residential receptors and the freight alignment, as well as overall density of existing sources. Where appropriate, the BAAQMD's (2012b, 2012c) distance multipliers were used to adjust risks from existing generators and gasoline-dispensing facilities. Total cumulative health risks at the representative location in each freight section were calculated by adding the background health risk sources to the health risk and hazard effects for the net change in health risk from the relocated freight service.

Table 10-1 shows cumulative cancer risk, chronic health hazard, and $PM_{2.5}$ concentrations at representative locations along the relocated freight sections.

[1] Presents the maximum incremental contribution from the relocated freight service, relative to existing conditions (see Table 7-20)
[2] BAAQMD has adopted both project- and cumulative-level thresholds for health risks. BAAQMD's cumulative thresholds are used in this analysis.

The San Jose Diridon and Gilroy stations and the MOWS and MOWF would have emergency generators that would be used in the event of a power outage. The MOWF would also use diesel-powered off-road equipment, vehicles, and locomotives to support maintenance and repair activities. The new East Gilroy Station would serve diesel-powered buses.[30] Table 10-2 shows the maximum cumulative risks and $PM_{2.5}$ concentrations near HSR stations and the MOWF.[31]

HI = hazard index
$PM_{2.5}$ = particulate matter 2.5 microns or less in diameter
µg/m³ = micrograms per cubic meter
< = less than
[1] Presents the maximum incremental project contribution (see Table 7-21). These risks do not exceed BAAQMD's project-level thresholds.
[2] A project-specific cancer risk and chronic health hazard assessment was not conducted since BAAQMD Regulation 2, Rule 5, Section 302, prohibits generator use if they would result in cancer or acute hazard impacts in excess of BAAQMD's health risk thresholds of significance.
[3] There are no receptors within 1,000 feet of the South Gilroy MOWF. Accordingly, a health risk assessment is not required, consistent with BAAQMD (2017a) guidance.
[4] BAAQMD has adopted both project- and cumulative-level thresholds for health risks. BAAQMD's cumulative thresholds are used in this analysis.

[30] Bus service levels at the existing Diridon and Downtown Gilroy Stations are constant into the future given that no operator has a funding plan to deliver more service. Accordingly, there would be no change in risk relative to existing conditions.
[31] There are no receptors within 1,000 feet of the South Gilroy MOWF. Accordingly, a health risk assessment is not required, consistent with BAAQMD (2017a) guidance.

As shown in Table 10-1, total cumulative cancer and noncancer chronic health hazards to sensitive receptors located near the relocated freight service would not exceed the BAAQMD's health risk thresholds. However, cumulative $PM_{2.5}$ exposure at certain locations is above the BAAQMD's threshold of 0.8 µg/m^3. The exceedances are the result of existing sources located within the vicinity of the freight tracks, as the freight relocation would reduce $PM_{2.5}$ concentrations at these locations relative to existing conditions. As shown in Table 10-2, total cumulative health risks to sensitive receptors located near the HSR stations and the MOWF would not exceed the BAAQMD's health risk thresholds.

10.2 Construction

Air quality construction effects associated with the project would be above the BAAQMD's and SJVAPCD's significance thresholds.

State: As described in Section 8.4, Construction Greenhouse Gas Emissions, construction of the project would result in a one-time increase in GHG emissions. These emissions are anticipated to be offset in 8 to 14 months of project operations because of reduced passenger vehicle travel on roadways. Based on this short offset time period, the overall GHG effects (construction plus operations) would be negative and would therefore be consistent with AB 32 and SB 32 goals.

Regional: The BAAQMD, MBARD, and SJVAPCD thresholds of significance may be used to evaluate criteria pollutant effects. Projects in excess of these significance thresholds would have a cumulatively considerable effect on air quality in the SFBAAB, NCCAB, and SJVAB because they would not be consistent with the BAAQMD's, MBARD's, and SJVAPCD's attainment strategies and would prevent the BAAQMD, MBARD, and SJVAPCD from achieving attainment of state and federal standards.

As discussed in Chapter 7, construction of Alternatives 1 through 4 would result in ROG and NO_X that would exceed BAAQMD's CEQA thresholds, and NO_X, CO, and PM_{10} emissions that would exceed SJVAPCD's CEQA thresholds. ROG, NO_X, and PM_{10} emissions would be reduced and offset in the BAAQMD and SJVAPCD, as applicable, through the purchase of offsets (AQ-MM#3 and AQ-MM#4). Because AQ-MM#3 and AQ-MM#4 would offset ROG, NO_X, and PM emissions to below air district thresholds or net zero, construction of the project would not have a cumulatively considerable effect on ROG, NO_X, and PM.

Pursuant to SJVAPCD's GAMAQI, emissions offsets procured through AQ-MM#4 cannot be used to mitigate CO effects. Accordingly, CO emissions would remain above SJVAPCD's CEQA threshold and cumulatively considerable even after implementation of all feasible mitigation.

Local: Emissions analysis at the local level includes the criteria pollutants PM_{10}, $PM_{2.5}$, NO_2, CO, SO_2, and TACs.

10.2.1 Criteria Pollutants

It is anticipated that construction activities would lead to new violations of the PM_{10} and $PM_{2.5}$ CAAQS and NAAQS, as well as potentially contribute to existing PM_{10} and $PM_{2.5}$ violations through exceedances of the SIL. Alternatives 1, 2, and 4 would also violate the 1-hour NO_2 NAAQS and CAAQS. Project features would minimize air quality impacts (AQ-IAMF#1 through AQ-IAMF#6), although emissions concentrations would still violate the ambient air quality standards and exceed the SIL.

10.2.2 TACs

A cumulative HRA was performed for portions of project construction located within the BAAQMD, consistent with air district requirements. Current MBARD and SJVAPCD guidance is to evaluate the potential risks associated from all project emission sources. Within the NCCAB and SJVAB, emission sources outside the project footprint should not be included in the cumulative assessment. If the project assessment demonstrates that potential health impacts are less than significant, one could conclude that the project would have a less than cumulatively significant impact (Siong 2011; Frisbey 2017). As discussed in Section 7.10, Construction Health Risk

Assessment, construction of the project in the NCCAB and SJVAB would not exceed the MBARD's nor SJVAPCD's project-level health risk thresholds.

The construction cumulative HRA in the BAAQMD was performed using the method described in Chapter 6 for near- and long-term operational impacts. The BAAQMD's Google Earth and GIS raster files were used to screen the HSR alignment and select one 1,000-foot area per subsection to analyze cumulative health risks. Note that in some locations, two areas were analyzed to capture the greatest ambient cancer risk and $PM_{2.5}$ concentration, which occur at different locations within the 1,000-foot radius. Total cumulative health risks at the representative location(s) in each subsection were calculated by adding the background health risks sources to the health risk and hazard impacts for project construction. Tables 10-3 through 10-6 summarize the maximum cumulative cancer risk, chronic health hazard, and $PM_{2.5}$ concentrations at the representative locations in the subsections. Appendix C provides further details on the ambient sources included in the cumulative analysis.

HI = hazard index
$PM_{2.5}$ = particulate matter 2.5 microns or less in diameter

µg/m^3 = micrograms per cubic meter
HSR = high-speed rail
[1] Presents the maximum health risk from HSR construction (see Table 7-32). These risks do not exceed BAAQMD's project-level thresholds.
[2] BAAQMD has adopted both project- and cumulative-level thresholds for health risks. BAAQMD's cumulative thresholds are used in this analysis.

The combined effects of the electrified passenger rail service, displacement of VMT and air travel, and motor vehicle and stationary source turnover represent the new emissions paradigm to which receptors would be exposed. Although there are areas of the RSA with greater existing health risks, the addition of HSR service would achieve health risk reductions in the RSA, which also would constitute a localized air quality benefit. Nevertheless, combined total cumulative cancer risks and noncancer impacts on sensitive receptors located near the project footprint would exceed the BAAQMD's thresholds. The exceedances are primarily the result of existing ambient sources, as the project's relative contribution to the exceedances of the screening threshold is less than the BAAQMD's project-level heath thresholds and is minor compared to health risks from existing sources.

10.3 Combined Construction and Operations Cumulative Health Risk Assessment

Individuals currently residing near the project corridor are exposed to a certain amount of pollution (representative of ambient risks described in Tables 10-1 through 10-6). If that individual remains in the same location during and after construction, they would be exposed to project-generated DPM during construction and then any incremental changes in risk from project-generated DPM during operations. Analysts conservatively estimated the potential lifetime risks to long-term residents that may be present during both construction and operations. Tables 10-7 through 10-10 show the results of the analysis and compare the risks to BAAQMD's cumulative thresholds. There would be no freight relocation or station operations in the Pacheco Pass Subsection. Accordingly, there is no potential for combined risk from construction and operations, and as such, the subsection is not included in the tables.

As shown in Tables 10-7 through 10-9, total cumulative health risks during construction and long-term operations would not exceed BAAQMD's thresholds at locations where a single receptor could be located during both construction and operation. Note that these receptors may be in a different location than those analyzed for the construction-only analysis in Tables 10-3 through 10-6. Accordingly, ambient or background risks differ among the analyses. Table 10-10 shows that cumulative $PM_{2.5}$ exposure would exceed BAAQMD's threshold in all subsections under Alternative 4. The exceedances are primarily the result of existing sources in the vicinity of the freight tracks, because the freight relocation would either result in minimal $PM_{2.5}$ (<0.1 µg/m^3) or reduce $PM_{2.5}$ concentrations at these locations relative to existing conditions.

11 CONFORMITY ANALYSIS

Projects requiring approval or funding from federal agencies that are in areas designated as nonattainment or maintenance for the NAAQS may be subject to the USEPA's Conformity Rule. The two types of federal conformity are Transportation Conformity and General Conformity.

Conformity refers to conforming to, or being consistent with, SIP for compliance with the CAA. The USEPA's Conformity Rule requires SIP conformity determinations on transportation plans, programs, and projects before they are approved or adopted (i.e., eliminating or reducing the severity and number of violations of the NAAQS and achieving expeditious attainment of such standards [40 C.F.R. Part 93]). Federal activities, such as federally sponsored projects, may not cause or contribute to new violations of air quality standards, exacerbate existing violations, or interfere with timely attainment or required interim emission reductions toward attainment.

Transportation conformity applies to those projects that will have FHWA or Federal Transit Administration (FTA) funding or require FHWA/FTA approval. General Conformity applies to those projects that will have funding or require approval from any federal agency other than the FHWA or FTA.

The FRA and USEPA have determined that General Conformity may be applicable to the project. The federal lead agency for the project is the FRA, and FHWA or FTA involvement is not anticipated other than incidental FHWA or FTA funding for joint-benefit components.

If the FHWA or FTA funds a component of the HSR, or if a minor action is required to approve the project, such as the need for an FHWA-approved grade crossing, it is anticipated that this project element would be added to the affected area's Regional Transportation Improvement Program or RTP for transportation conformity purposes. However, conformity of elements of the overall HSR system is addressed through application of the General Conformity Rule and requirements. Both General Conformity and Transportation Conformity, as they relate to the project, are discussed in this chapter.

11.1 General Conformity

The USEPA has established General Conformity *de minimis* thresholds (in tons per calendar year) for each criteria pollutant to determine whether projects are subject to conformity determination requirements. If the emissions generated by construction or operations of a project (on an area-wide basis) are less than these threshold values, the effects of the project are not considered to be significant, and no additional analyses are required to satisfy General Conformity. If the emissions are greater than these values, compliance with the General Conformity Rule must be demonstrated by one or more of several prescribed methods.

Under federal designations, the RSA is currently designated as extreme and marginal nonattainment for 8-hour O_3 in the SJVAB and SFBAAB, respectively; serious/moderate nonattainment for $PM_{2.5}$ in the SFBAAB and SJVAB; and maintenance for PM_{10} in the SJVAB. As such, the FRA is required to demonstrate project-level compliance with the General Conformity Rule for NO_X and VOC (O_3 precursors), $PM_{2.5}$, PM_{10}, and SO_2 ($PM_{2.5}$ precursor) if project-related emissions of these pollutants in the SFBAAB or SJVAB would exceed the General Conformity *de minimis* thresholds.

As shown in Section 7.4, Total Operations Emissions, the total regional emissions for all of the applicable pollutants would be lower during project operations than under No Project conditions (and would therefore not exceed the *de minimis* emission thresholds). Accordingly, only emissions generated during the construction phase need to be compared to the conformity threshold levels to determine conformity compliance. As shown in Section 7.9, Construction Mass Emissions Analysis, construction emissions, compared to the General Conformity applicability rates, are as follows:

- Annual estimated NO_X emissions in the SJVAB are greater than the applicability rate of 10 tons per year for all years of construction between 2022 and 2028 for all project alternatives with implementation of IAMFs.

- Annual estimated NO_X emissions in the SFBAAB are greater than the applicability rate of 100 tons per year in 2024 under Alternatives 1 and 3 and for all years of construction between 2023 and 2025 under Alternatives 2 and 4 with implementation of IAMFs.
- Annual estimated VOC, SO_2, PM_{10}, and $PM_{2.5}$ emissions are less than the applicability rates in the SFBAAB and SJVAB with implementation of IAMFs.

As such, a General Conformity Determination is required for the project for NO_X for the years during construction when the emissions would exceed the *de minimis* thresholds in the SFBAAB and SJVAB. The General Conformity Determination can be achieved using one of the following methods:

- Demonstrating that the direct and indirect emissions are specifically identified in the relevant implementation plan
- Obtaining a written statement from the entity responsible for the implementation plan that the total indirect and direct emissions from the action, along with other emissions in the area, would not exceed the total implementation plan emission budget
- Fully offsetting the total direct and indirect emissions to net zero by reducing emissions of the same pollutant in the same nonattainment or maintenance area

Compliance with the General Conformity Rule for the APA is required before construction of the project, but may be completed concurrent with EIR/EIS certification. Demonstrating compliance with the General Conformity Rule will not change the results of the analysis described in this report.

Appendix 3.3-B in the Draft EIR/EIS contains the draft General Conformity Determination for the project. The FRA demonstrates in the determination that the emissions of NO_X (a precursor to O_3) caused by the construction of the project would not result in an increase in regional NO_X emissions. This would be achieved by offsetting the NO_X emissions generated by construction of the project in a manner consistent with the General Conformity regulations.

The offsets are anticipated to be accomplished through an agreement with the BAAQMD and a VERA between the Authority and the SJVAPCD. The requirement for the agreement and VERA would be implemented as part of the project as described in the mitigation measures identified in Chapter 9.

The FRA is issuing the draft General Conformity Determination for public and agency review as part of the Draft EIR/EIS. Any comments on the draft General Conformity Determination would be addressed in the final General Conformity Determination, which would be included in the Final EIR/EIS for the project.

11.2 Transportation Conformity

Transportation conformity is an analytical process required for all federally funded transportation projects, but it does not apply to the project. Under the 1990 CAA amendments, the U.S. Department of Transportation cannot fund, authorize, or approve federal actions to support programs or projects that are not first found to conform to the SIP for achieving the goals of the CAA requirements. Conformity with the CAA takes place at both the regional and project levels.

The project is not subject to the Transportation Conformity Rule. However, if the project requires future actions that meet the definition of a project element subject to Transportation Conformity, additional determinations and associated analysis would be completed as required.

Project Characteristics - Adjusted for SB 350
Vehicle Trips - Employee + haul (trip distance weighted based on H-W employee miles + 120 haul truck miles)
Fleet Mix - Reweighted for LDA/LDT/MCY/HHD
Stationary Sources - Emergency Generators and Fire Pumps - Back Up Generator

East Gilroy Transit Calculations

Assumptions

Parameter	Result	Unit
Bus trips	107	per day
Idle time	5	minutes per trip
Travel distance	2000[a]	feet
Total station idle	535	min/day
Total station VMT	41	miles/day

[a] *Assumes 1,000 foot segment upon entry and exit*

Conversions/Defaults

Parameter	Result
Pounds per gram	0.0022
Tons per pound	0.0005
Days per year	365
miles per feet	0.0002

EMFAC2017 Emission Factors[a]

Pollutant/process	Factor	Unit
PM10, running	0.00544	grams/mile
PM2.5, running	0.00521	grams/mile
PM10, idling[b]	0.00057	grams/min
PM2.5, idling[b]	0.00055	grams/min

[a] *Based on outputs for Santa Clara County, 2029, DSL UBUS at 15 miles per hour*

[b] *Convert the 5-mph factor to grams per idle-min assuming 0.08333 miles are traveled per minute*

Emissions

	Grams per Day		Pounds per Day		Tons per Year	
Source	PM10	PM2.5	PM10	PM2.5	PM10	PM2.5
Idle	0.3073	0.2940	0.0007	0.0006	0.0001	0.0001
Approach/Depart	0.2205	0.2110	0.0005	0.0005	0.0001	0.0001
